STUDIES ON A BACTERICIDAL AGENT EXTRACTED FROM A SOIL BACILLUS

I PREPARATION OF THE AGENT ITS ACTIVITY IN VITRO

By RENÉ J. DUBOS, PH.D.

(From the Hospital of The Rockefeller Institute for Medical Research)

(Received for publication, April 17, 1939)

Microorganisms perform a vast number of biochemical reactions, many of which are not known to occur in the animal and plant kingdoms (1). On the basis of present knowledge it is conceivable that one may find in nature microbial species endowed with catalysts capable of activating almost any type of biochemical reaction. During the past few years, this point of view has found its application in the isolation of soil microorganisms which selectively attack certain substances of interest to the biochemist (2) and to the immunologist (3-8). It may be recalled in particular that soluble polysaccharides, extracted from several bacterial pathogens, have been found to be decomposed by certain microbial species, although the same substances are resistant to the action of all known enzymes of animal and plant origin.

It appeared possible that there also exist in nature microorganisms capable of attacking not only isolated soluble components of other bacterial cells, but also the intact living cells themselves. Actually we have isolated from soil a spore bearing bacillus which attacks and lyses the living cells of several species of Gram positive microorganisms. The present paper describes the isolation of this new soil bacillus, and the preparation, properties, and activity of the soluble agent by means of which it attacks and lyses the living cells of the susceptible, Gram positive species.

EXPERIMENTAL

Isolation of a Sporulating Bacillus Capable of Lysing the Living Cells of Gram-Positive Microorganisms—The method employed for the discovery of microorganisms capable of attacking certain definite organic compounds has already been described (2, 3). It is based on the assumption that all organic matter added to the soil eventually undergoes decomposition through the agency of microorganisms. In the present case, it was hoped

that the addition to soil of living cultures of Gram-positive cocci would result in the development of a selective soil flora capable of attacking the living cells of these bacterial species

Soil samples of neutral reaction, obtained from a number of different sources, were pooled, and mixed with alkaline phosphate, ammonium sulfate, and an excess of calcium carbonate. The mixed sample was kept at about 70 per cent of its moisture-holding capacity and incubated at 30°C for a few weeks in order to bring about the decomposition of most of the organic matter originally present.

Staphylococci, pneumococci (R variants), and group A hemolytic streptococci (glossy variants) were grown in beef infusion peptone broth and centrifuged, the living cells, resuspended in small volumes of distilled water, were added to the soil sample. After two years, during which this process was repeated at irregular intervals of time, a small amount of the soil preparation (2 gm) was added to 10 cc of mineral medium ($M/20$ K_2HPO_4 , $M/30$ NaH_2PO_4 , $M/100$ $(NH_4)_2SO_4$, tap water) to which had been added the living cells recovered from 150 cc of staphylococcus culture. This suspension, containing soil and staphylococci, was incubated in shallow layers at 30°C. After 48 hours incubation, stained films of the bacterial suspension revealed advanced lysis of the staphylococci and the presence of a mixed bacterial flora. A small amount of the same suspension was now transferred to a similar medium and incubated under the same conditions. Again, lysis of the staphylococci was observed within 48 hours. A few more transfers were sufficient to eliminate most of the microbial species originally present in the soil used as inoculum. By plating on peptone agar, it was finally possible to isolate in pure culture a Gram-positive bacillus capable of lysing living staphylococci resuspended in the mineral medium described above.

Description of the Organism —The organism is a motile spore-bearing bacillus measuring in average $4 \times 0.5 \mu$. The spores are terminal, oval, they resist heating at 80°C but are killed at boiling temperature.

Very young cells of the bacillus retain the Gram stain, but they soon lose this characteristic and appear then as Gram-negative rods. This change in staining reaction is probably associated with the fact that cultures undergo autolysis very rapidly (24 to 48 hours), giving rise to shadow cells with intensely stained granules, Gram-negative detritus, and a mass of oval spores.

The organism grows readily and abundantly on peptone media, especially when incubation is carried out in shallow layer at 37°C. No gas is formed in sugar peptone media, and the culture does not become acid (the following substrates were tested, arabinose, dextrose, dulcitol, inulin, lactose, mannose, mannite, rhamnose, saccharose, salicin, sorbitol, xylose). Litmus milk becomes alkaline. The fact that indicators do not reveal the production of acid does not necessarily mean, however, that the substrates are not fermented by the culture. It has been observed that the growth of the bacillus in peptone solution renders the medium very alkaline (pH 9.0) and it is possible that the production of alkaline substances may mask the production of organic acids from the sugars added to the peptone.

The organism liquefies gelatin and gives a diffuse zone of hemolysis on blood agar plates. It gives a negative V.P. test and forms H_2S on lead acetate agar medium. Catalase production is very abundant.

Preparation and Properties of a Soluble Bacterial Extract Which Attacks the Living Cells of Gram Positive Microorganisms—As stated above, the spore bearing bacillus just described is capable of lysing suspensions of living staphylococci. The lysis is caused by an agent which is found in solution in autolysates of cultures of the soil bacillus. When very young cultures (12 to 18 hours) of the bacillus are used, the active agent is found in the bacterial bodies, it can then be obtained in solution by collecting the bacterial cells, and allowing them to autolyze in an aqueous medium. As the culture becomes older, however, more and more of the active material is found in solution in the culture medium and, after 72 hours (when practically all cells have autolyzed) only a small percentage of the activity is found associated with the cellular material.

The active principle is quantitatively precipitated at pH 4.5, the precipitate, redissolved at neutral reaction, exhibits the activity of the original solution.

On the basis of these observations, the following method has been employed for the preparation and concentration of the active extract used in the experiments described in this and the following paper.

The organism is grown in a medium consisting of 1 per cent acid hydrolysate of casein in tap water, at pH 7.0. The culture is incubated in shallow layer (3 cm.) for 3 to 4 days at 37°C. At the end of the incubation period, stained films of the culture show the presence of Gram negative shadow forms and of large numbers of spores and the reaction of the medium has become alkaline (pH 9.0). The culture is then centrifuged for 1 hour at 3,500 R.P.M. The clear supernatant fluid is separated, and acidified to pH 4.5 (this requires about 4 cc. of concentrated HCl per liter of autolysate). A faint precipitate forms; it is separated by centrifugation or filtration and redissolved at neutral reaction.

Work is now in progress toward further purification of the active material, a complete description of its properties and composition is therefore reserved for the future, when pure preparations are available. It may be stated, however, that the preparations obtained by the technique just described give all the protein tests and contain 14.5 per cent nitrogen. The active principle does not dialyze through collodion membranes, it retains its activity after 10 minutes heating at 90°C at pH 2.0 and pH 9.0. It is also resistant to the action of pepsin, of crystalline trypsin and chymotrypsin, and of crude trypsin. It must be pointed out, however, that although treatment with heat or with proteolytic enzymes does not inactivate the bactericidal agent, it renders it insoluble in neutral buffer solutions.

Filtration through Berkefeld candles (V) gives preparations which are capable of lysing the susceptible bacterial species although much activity is lost during the process. Filtration through Chamberland filters or asbestos pads has always resulted in complete loss of activity.

The Effect of the Soluble Bacterial Extract upon the Living Cells of Several Microbial Species—The effect of the bacterial extract upon different microbial species has been studied under a variety of conditions which will be described in this and other publications. It is permissible to state at the present time, however, that the bacterial extract has been found to exert a marked bactericidal effect upon all the Gram-positive species thus far tried, whereas all the Gram-negative bacilli have remained unaffected. Gram-negative cocci and acid-fast bacilli have not yet been tried.

The following microbial species have been studied.

A Gram-positive species (all susceptible to the bactericidal effect of the extract) *Diplococcus pneumoniae* Five strains of virulent encapsulated pneumococci (Types I, II, III, V, and VIII). Three strains of avirulent rough pneumococci (derived from Types I, II, III). *Streptococcus hemolyticus* Eight matt and glossy strains of group A (types 1, 3, 6, 14, 20). Three virulent strains of group C. Three strains of group D (cheese streptococci). *Streptococcus viridans* Two strains. Indifferent (gamma) streptococci Two strains. *Staphylococcus aureus* One rabbit virulent strain, one mouse virulent strain. Unidentified culture of spore-bearing Gram-positive bacillus *Saccharomyces cerevisiae*.

B Gram-negative species (not susceptible to the bactericidal effect of the extract) *Escherichia coli* *Eberthella typhi* *Salmonella paratyphi* *Klebsiella pneumoniae* type B *Hemophilus influenzae* Unidentified culture of spore-bearing Gram-negative bacillus.

The activity of the bacterial extract upon the cells of the different microbial species, as measured by lysis and loss of viability, was studied in the following experiments.

The test cultures were grown for 8 hours in meat infusion peptone broth, the cells were separated by centrifugation and resuspended in phosphate buffer (pH 7.6) to give suspensions containing about 10^9 cells per cc. The suspensions, distributed in 1 cc amounts into test tubes, were treated with different amounts of bacterial extract (preparation NS7) and made up to a final volume of 2 cc with phosphate buffer (see Table I).

After 3 hours incubation at 37°C the different preparations were observed for the occurrence of lysis (turbidity readings, confirmed by microscopic examinations), and streaked on blood agar plates to determine the effect of the bacterial extract on the viability of the cells (Table I).

The results presented in Table I indicate that the soluble bacterial extract exerts a bactericidal effect on all the Gram-positive microorganisms so far tested. Unequivocal evidence of lysis was recognized only in the case of pneumococci, staphylococci, and a Gram-positive spore-bearing rod. The soluble extract exerted no bactericidal effect, nor did it cause the lysis of any of the Gram-negative species.

The bactericidal effect of the extract was concluded from the inability of the treated susceptible cells to grow on subsequent transfer to blood agar plates. In other tests, these results were confirmed by inoculating the cells into liquid media, where they failed to multiply, or by injecting the virulent species into susceptible animals, which they failed to kill.

It is worth emphasizing the comparative effects of different amounts of extract in causing the death or the lysis of the various microorganisms. In the case of pneumococci, staphylococci, and the Gram-positive spore-bearing rods, death of the cell is accompanied by lysis. On the contrary, streptococci do not lyse although they are susceptible to the bactericidal effect of the extract, in fact, no lysis of the streptococci is observed even when they are treated with 100 times the minimal amount of extract required to kill the cells. It is also worth noting that staphylococci, although much more resistant than group A hemolytic streptococci to the killing effect of the extract, undergo lysis very readily.

It appears therefore that no parallelism exists between lytic effect and bactericidal effect, in fact, it will be shown later in this article that lysis is only a secondary process, caused by the action of the autolytic enzymes of the cells, and follows some other primary injury inflicted by the bactericidal agent.

Several attempts have been made to compare the effect of the bactericidal agent upon pneumococci and upon group A hemolytic streptococci in different culture phases (rough and smooth, glossy and matt variants). This was studied by determining the minimal amount of extract required to kill the same number of cells of different species in a given time, or by measuring the length of time required by a same amount of extract to kill the same number of cells. Under these conditions no difference could be found between R and S pneumococci, or between glossy, matt avirulent, and matt virulent streptococci, irrespective of type derivation. Furthermore pneumococci, group A and group C hemolytic streptococci, green and indifferent streptococci, were all found to be equally susceptible to the bactericidal agent.

The Inhibitory Effect of the Bactericidal Agent on the Glucose Dehydrogenase of Microorganisms—The results presented in Table I indicate that the

minimal effective dose of the bactericidal agent is not the same for all the microbial species. Yeast and cheese streptococci require the largest amount (1 to 5 mg per 10^9 cells), next come the staphylococci (0.1 mg per 10^9 cells), the pneumococci, hemolytic streptococci of group A and C, green and indifferent streptococci, are all killed by very small amounts of extract (0.01 mg). In a general way, it can be said that the resistance of the various microbial species to the bactericidal agent varies in the order of their metabolic activity, as measured by their ability to reduce methylene blue in the presence of glucose: yeast and cheese streptococci (group D) metabolize more actively than staphylococci, which in their turn are more active than pneumococci and hemolytic streptococci of group A. This parallelism suggested that the primary toxic effect of the bactericidal agent might be directed against the dehydrogenase system of the microbial cell, some preliminary experiments were instituted to test this point.

Microbial suspensions containing approximately 10^9 cells per cc were used. They were distributed in 3 cc amounts into test tubes and were treated with different amounts of the bactericidal agent (Table I). The mixtures were incubated for 3 hours at 37°C . Methylene blue (1 cc. of 0.002 M solution) and glucose (1 cc. of 10 per cent solution) were then added, and the mixtures, sealed with vaseline, were incubated at 37°C . The rate of reduction of the dye was observed. Although the data concerning the experimental procedure and the results obtained, will be presented *in extenso* in another publication, a general summary of the final results is incorporated in Table I.

It is clear that, in the case of all the Gram positive organisms, incubation of the microbial cells with sufficient amounts of the bactericidal extract results in an inhibition of methylene blue reduction. The glucose dehydrogenase of the Gram negative bacilli, on the contrary, is not affected by the same treatment.

In all cases, the minimal amount of bactericidal extract required to kill the microbial cells is also sufficient to inhibit their reducing action. In other words, the loss of viability appears to be quantitatively related to the inactivation of the glucose dehydrogenase of the cell.

Inhibition of Growth by the Bactericidal Agent—The lytic effect of the soluble agent upon pneumococci and staphylococci, and its bactericidal effect upon Gram positive organisms in general, can be observed not only when the susceptible cells are resuspended in buffer solution, but also in the presence of meat infusion, peptone, serum, and ascitic fluid. It was to be expected, therefore, that the extract would inhibit the growth of the susceptible species in culture media.

Inhibition of growth has in fact been observed in the case of all the Gram positive organisms mentioned in Table I. A single example will illustrate

the activity of the extract in this respect. Test tubes containing 5 cc of meat infusion peptone broth were inoculated with 0.03 cc of a pneumococcus culture (D39R), and treated with different amounts of bactericidal agent (preparation NS7). Full growth had developed within 12 hours in the untreated control tubes whereas it took 24 hours for growth to appear in the tube which had received 0.000,01 mg of extract. No growth developed in the tubes which received 0.000,1 mg (or more) of the same preparation. On the contrary, no inhibition or retardation of growth was observed with any of the Gram-negative bacilli, for instance *Escherichia coli*, *Klebsiella pneumoniae*, *Eberthella typhi*, grow normally in the presence of large amounts of extract, even when an inoculum as small as 10^{-7} cc is used.

DISCUSSION

The bactericidal agent described in the present paper is associated with a protein fraction which precipitates out of solution at pH 4.5. Heating at 90°C, or digestion with proteolytic enzymes, renders the active fraction insoluble, but does not in any way affect its lytic or bactericidal power, as can be shown by adding the suspension of insoluble material to the susceptible bacterial species. It is possible therefore, that the active substance itself is not a protein, but that the protein with which it is associated determines its solubility properties.

Although the agent exerts a bactericidal effect on the cells of all the Gram-positive species so far tested, its lytic effect has been observed only against pneumococci, staphylococci, and an unrelated Gram-positive spore-bearing bacillus. It is likely, therefore, that the death of the cell does not result from a lytic action of the extract, but that on the contrary, lysis is only a secondary process. The bacteriological literature offers several examples of "secondary lysis" following treatment with various antiseptics (heavy metals, formaldehyde, iodine, bile salts, toluol, acetone, etc.) (9, 10). In fact, the "bile solubility" of pneumococci is a good example of this phenomenon. Bile salts, unsaturated fatty acids, do not by themselves lyse the pneumococci, they inflict upon the cell an injury which destroys some essential metabolic function, without at the same time destroying the autolytic enzymes, the autolytic system, held in abeyance in the normal living cell, then begins to function, and autolysis follows (11, 12).

It is worthy of notice that group A hemolytic streptococci are known to be very resistant to normal autolysis, staphylococci autolyze more rapidly and pneumococci most rapidly of all. It has now been found that the

bactericidal agent considered in the present paper "lyzes" pneumococci most readily, staphylococci somewhat more slowly, and streptococci little or not at all, even though group A hemolytic streptococci are as susceptible as pneumococci to the bactericidal effect of the agent. Furthermore, it has been found that the bactericidal agent does not lyse the cells of pneumococci or staphylococci in which the autolytic enzymes have been destroyed by heating, or by treatment with formaldehyde. All these facts, when taken together, suggest that the bactericidal agent exerts a toxic action upon the living cells of the susceptible species and that lysis, when it occurs, is only a secondary process, caused by the cells' own autolytic enzymes.

How then does the bactericidal agent exert its toxic effect? It has been found that the minimal amount of extract which causes the death of the cell also destroys its ability to reduce methylene blue in the presence of glucose. This is not, however, sufficient evidence to establish that the inhibition of the glucose dehydrogenase is the cause of cell death. It remains possible that both effects are the common result of some other primary injury, as yet unrecognized. In the analysis of this question, it may be important to keep in mind that the minimal amount of extract required to kill a given number of cells is the same whether the test is carried out with pneumococci, or hemolytic streptococci of group A and C, or green and indifferent streptococci, irrespective of type derivation and culture phase (rough and smooth, matt and glossy variants). This observation suggests that the effect of the bactericidal agent is directed against a cellular structure or function which is common to all these bacterial species.

Furthermore, it is worth emphasizing again that the extract appears to be effective only against Gram positive microorganisms. No lytic or bactericidal effect, no inhibition of glucose dehydrogenase, no retardation of growth could be observed with any of the Gram negative bacilli so far tested (Gram negative cocci and acid fast bacilli have not yet been tested). Many examples are already known of differential toxic action of antiseptics upon Gram positive and Gram negative species (13-15). In fact, the Gram stain appears to divide the microbial world into two groups which differ widely, not only in several of their physiologic properties, but also in the chemical structure of the cell (16). Professor Christian Gram, who introduced in bacteriology the staining technique which bears his name, died recently (17). It may be proper at this time to suggest that the Gram reaction, which has proved of such great importance in the identification and classification of microbial species, may in the future serve as a guide in the study of fundamental problems of bacterial physiology and cytology.

the activity of the extract in this respect. Test tubes containing 5 cc of meat infusion peptone broth were inoculated with 0.03 cc of a pneumococcus culture (D39R), and treated with different amounts of bactericidal agent (preparation NS7). Full growth had developed within 12 hours in the untreated control tubes whereas it took 24 hours for growth to appear in the tube which had received 0.000,01 mg of extract. No growth developed in the tubes which received 0.000,1 mg (or more) of the same preparation. On the contrary, no inhibition or retardation of growth was observed with any of the Gram-negative bacilli, for instance *Escherichia coli*, *Klebsiella pneumoniae*, *Eberthella typhi*, grow normally in the presence of large amounts of extract, even when an inoculum as small as 10^{-7} cc is used.

DISCUSSION

The bactericidal agent described in the present paper is associated with a protein fraction which precipitates out of solution at pH 4.5. Heating at 90°C , or digestion with proteolytic enzymes, renders the active fraction insoluble, but does not in any way affect its lytic or bactericidal power, as can be shown by adding the suspension of insoluble material to the susceptible bacterial species. It is possible therefore, that the active substance itself is not a protein, but that the protein with which it is associated determines its solubility properties.

Although the agent exerts a bactericidal effect on the cells of all the Gram-positive species so far tested, its lytic effect has been observed only against pneumococci, staphylococci, and an unrelated Gram-positive spore-bearing bacillus. It is likely, therefore, that the death of the cell does not result from a lytic action of the extract, but that on the contrary, lysis is only a secondary process. The bacteriological literature offers several examples of "secondary lysis" following treatment with various antiseptics (heavy metals, formaldehyde, iodine, bile salts, toluol, acetone, etc.) (9, 10). In fact, the "bile solubility" of pneumococci is a good example of this phenomenon. Bile salts, unsaturated fatty acids, do not by themselves lyse the pneumococci, they inflict upon the cell an injury which destroys some essential metabolic function, without at the same time destroying the autolytic enzymes, the autolytic system, held in abeyance in the normal living cell, then begins to function, and autolysis follows (11, 12).

It is worthy of notice that group A hemolytic streptococci are known to be very resistant to normal autolysis, staphylococci autolyze more rapidly and pneumococci most rapidly of all. It has now been found that the

the activity of the extract in this respect. Test tubes containing 5 cc of meat infusion peptone broth were inoculated with 0.03 cc of a pneumococcus culture (D39R), and treated with different amounts of bactericidal agent (preparation NS7). Full growth had developed within 12 hours in the untreated control tubes whereas it took 24 hours for growth to appear in the tube which had received 0.000,01 mg of extract. No growth developed in the tubes which received 0.000,1 mg (or more) of the same preparation. On the contrary, no inhibition or retardation of growth was observed with any of the Gram-negative bacilli, for instance *Escherichia coli*, *Klebsiella pneumoniae*, *Eberthella typhi*, grow normally in the presence of large amounts of extract, even when an inoculum as small as 10^{-7} cc is used.

DISCUSSION

The bactericidal agent described in the present paper is associated with a protein fraction which precipitates out of solution at pH 4.5. Heating at 90°C , or digestion with proteolytic enzymes, renders the active fraction insoluble, but does not in any way affect its lytic or bactericidal power, as can be shown by adding the suspension of insoluble material to the susceptible bacterial species. It is possible therefore, that the active substance itself is not a protein, but that the protein with which it is associated determines its solubility properties.

Although the agent exerts a bactericidal effect on the cells of all the Gram-positive species so far tested, its lytic effect has been observed only against pneumococci, staphylococci, and an unrelated Gram-positive spore-bearing bacillus. It is likely, therefore, that the death of the cell does not result from a lytic action of the extract, but that on the contrary, lysis is only a secondary process. The bacteriological literature offers several examples of "secondary lysis" following treatment with various antiseptics (heavy metals, formaldehyde, iodine, bile salts, toluol, acetone, etc.) (9, 10). In fact, the "bile solubility" of pneumococci is a good example of this phenomenon. Bile salts, unsaturated fatty acids, do not by themselves lyse the pneumococci, they inflict upon the cell an injury which destroys some essential metabolic function, without at the same time destroying the autolytic enzymes, the autolytic system, held in abeyance in the normal living cell, then begins to function, and autolysis follows (11, 12).

It is worthy of notice that group A hemolytic streptococci are known to be very resistant to normal autolysis, staphylococci autolyze more rapidly and pneumococci most rapidly of all. It has now been found that the

SUMMARY

A Gram-positive, spore-bearing, aerobic bacillus, capable of lysing the living cells of many Gram-positive microbial species, has been isolated from soil

Cultures of this soil bacillus in peptone media release during autolysis a soluble agent which exerts a bactericidal effect on all the Gram-positive microorganisms so far tested, and inactivates their glucose dehydrogenases. It also inhibits the growth of the susceptible species in culture media.

Several of the Gram-positive species undergo lysis when incubated with the bactericidal agent. It appears however, that lysis is only a secondary process, due to the autolytic enzymes of the susceptible cells, and that it follows upon some other primary injury caused by the active agent.

The bactericidal agent is ineffective against all the Gram-negative bacilli so far tested.

Addendum—The bactericidal agent described in the present paper has now been obtained in a form free of protein, the new purified preparations are about 50 to 100 times more active, both *in vitro* and *in vivo*, than the ones used in the experiments which have just been recorded.

D = death of the animal, the numeral indicates number of hours before death

The results presented in Table II show that, with 3 consecutive treatments at 24 hour intervals of time and comprising in all 4 mg of agent, it was possible to protect many mice against 0.1 and 0.01 cc of cultures of pneumococci of maximum virulence, in all cases the untreated control mice, inoculated with 0.000,000,01 cc of culture or with larger infective doses, died in less than 72 hours.

In order to study the comparative effectiveness of the bactericidal agent against the different types of pneumococci, an effort was made in the following experiment to determine the minimal amount of agent that would protect mice against the same infective dose of pneumococci of different types.

The results presented in Table II show that, with 3 consecutive treatments at 24 hour intervals of time and comprising in all 4 mg. of agent, it was possible to protect many mice against 0.1 and 0.01 cc. of cultures of pneumococci of maximum virulence, in all cases the untreated control mice, inoculated with 0.000,000,01 cc. of culture or with larger infective doses, died in less than 72 hours.

In order to study the comparative effectiveness of the bactericidal agent against the different types of pneumococci, an effort was made in the following experiment to determine the minimal amount of agent that would protect mice against the same infective dose of pneumococci of different types.

Titration of the Bactericidal Agent against Different Types of Pneumococci—Groups of 4 mice each were inoculated with 0.001 cc of 8 hour cultures of pneumococci of Types I, II, III, V, VIII. Within 10 minutes after inoculation each group was treated with 1 mg, 0.3 mg, or 0.1 mg respectively of the bactericidal agent. A second treatment with the same amount of extract (1 mg, 0.3 mg, and 0.1 mg respectively) was again given 24 hours later and the same dose repeated 48 hours after inoculation (Table III).

* The untreated control animals inoculated with 0.000,000,1 and 0.000,001 cc of culture died within 44 hours.

It is apparent from the results presented in Table III that 1 mg of extract administered daily on 3 consecutive days was sufficient to protect mice against infection with 0.001 cc of culture of pneumococci Types I, II, III, V, VIII. When the amount of extract was reduced to 0.3 mg or 0.1 mg daily, most animals died within the 6 day observation period, although they survived longer than the controls. One may conclude therefore, that the protective effect of the bactericidal agent is approximately the same against all virulent pneumococci so far tested, irrespective of specific type.

In the three experiments which have just been described, the first dose

of bactericidal agent was administered within 10 to 15 minutes after inoculation of the experimental animals with the infecting organism. In the following experiment an attempt was made to determine the curative effect of the bactericidal agent when administered several hours after injection of the infecting inoculum.

The Curative Effect of the Bactericidal Agent—Mice were inoculated with 0.000,01 cc of culture of Type I or Type III. They were divided into three groups which were treated with 2 mg of bactericidal agent respectively 2 hours, 5 hours, and 17 hours after infection. A second and a third dose of 1 mg each, were given 24 and 48 hours after the first treatment (Table IV).

The results presented in Table III show that mice inoculated with 1000 fatal doses of pneumococci Type I or Type III can be protected even when treatment with the bactericidal agent is delayed for several hours after

Protection has been obtained against cultures of the five different types of pneumococci (I, II, III, V, VIII) which have been used, these cultures were of maximum virulence since 0 000,000,01 cc was invariably fatal to mice within 72 hours. It is permissible to assume, therefore, that the agent will be found effective against experimental infection of mice with pneumococci of other types.

It is of special interest that the amount of bactericidal agent required to protect mice against a given amount of virulent culture is approximately the same irrespective of the type of pneumococcus used as infective agent. It is likely, therefore, that the action of the agent is directed against a structure or a function which is qualitatively and quantitatively similar in all pneumococci. The same conclusion had been derived from a study of

TABLE V

Effect of the Bactericidal Agent upon Experimental Infection of Mice with Klebsiella pneumoniae

Infective dose of <i>Klebsiella pneumoniae</i> type B	Treatment	Number of mice	Result

the action of the agent on pneumococci *in vitro*. As will be shown in a later publication, experiments carried out in collaboration with Dr. R. C. Lancefield have demonstrated that the agent also exerts a protective effect on experimental infection of mice with hemolytic streptococci of group A and C, on the contrary, it does not protect mice against *Klebsiella pneumoniae*, a Gram-negative organism, even when very small infective doses are used. This, again, is in agreement with the results of experiments *in vitro* in which a bactericidal effect was recognized against all the Gram-positive microorganisms so far tested, whereas the Gram-negative bacilli remained unaffected. There is little doubt, therefore, that the protective effect *in vivo* depends upon the same mechanism by which the bactericidal agent causes the death of the Gram-positive cells *in vitro*. It is interesting to contrast this direct bactericidal effect with the mechanism of the protection induced by a bacterial enzyme that hydrolyzes the capsular polysaccharide

This, again, is in agreement with the results of experiments *in vitro* in which a bactericidal effect was recognized against all the Gram-positive microorganisms so far tested, whereas the Gram-negative bacilli remained unaffected. There is little doubt, therefore, that the protective effect *in vivo* depends upon the same mechanism by which the bactericidal agent causes the death of the Gram-positive cells *in vitro*. It is interesting to contrast this direct bactericidal effect with the mechanism of the protection induced by a bacterial enzyme that hydrolyzes the capsular polysaccharide

of Type III *Pneumococcus* (2, 3) As described in earlier studies, this polysaccharidase does not in any way affect the viability of pneumococci, by decomposing the capsular substance of Type III organisms, however, it renders these bacterial cells susceptible to destruction by phagocytosis. The polysaccharidase does not attack the specific polysaccharides of other types of pneumococci, and consequently it protects only against infection with Type III organisms. On the contrary, the bactericidal agent considered in the present paper inhibits the growth of all Gram positive organisms so far tested, and exerts on them a direct bactericidal action *in vitro* and *in vivo*.

SUMMARY

In the first paper of this series, a description was given of a cell free extract, obtained from autolysates of a particular strain of a soil bacillus, which selectively inhibits the growth of all the Gram positive microorganisms so far tested, and exerts on them a bactericidal effect *in vitro*.

In the present study it is shown that the same agent protects white mice against infection with large numbers of virulent pneumococci. It also exerts a curative effect when administered to mice several hours after infection of the infecting organisms.

The degree of protection afforded, and the minimal effective dose of bactericidal agent, are approximately the same for all virulent pneumococci, irrespective of type specificity.

The bactericidal agent is entirely ineffective against infection with virulent Friedländer bacilli (type B). This agrees with the fact that the agent does not affect Gram negative bacilli *in vitro*.

The protective action exerted by the bactericidal agent against experimental pneumococcus infection depends upon the same mechanism which determines its bactericidal effect *in vitro*.

THE SIMULTANEOUS OCCURRENCE OF THE VIRUSES OF CANINE DISTEMPER AND LYMPHOCYTIC CHORIONMENINGITIS*

A CORRECTION OF "CANINE DISTEMPER IN THE RHEMUS MONKEY"

BY GILBERT DALLDORF M D

(From the Laboratories of Grasslands Hospital, Valhalla, New York)

(Received for publication, April 7, 1939)

The injection of suspensions of dog and ferret spleens from various generations of a particular serial passage of canine distemper was found to regularly produce a disease in *rhesus* monkeys which we believed to be *distemper* (1). Further work has shown this identification to be incorrect. The response in monkeys is not due to Carre's virus but to lymphocytic chorionmeningitis which has been simultaneously present with canine distemper virus in all of the samples of the source material tested. In a preliminary correction of the original report it was shown that each of two generations of the source material was capable of producing the clinical responses and lesions of lymphocytic chorionmeningitis in mice and guinea pigs. It was also shown that mice which had received suspensions of the material intravenously and recovered were subsequently resistant to a known strain of lymphocytic chorionmeningitis virus injected intracerebrally, and conversely that monkeys convalescent from infection with a known strain of virus were resistant to the same dog spleen suspensions which were pathogenic for normal monkeys (2). Having failed at that time to identify the second virus serologically and because it seemed of particular importance that its presence in the source material be thoroughly established, two other samples were examined. The study of these forms the substance of the present report. Certain observations which seem to explain some of the circumstances which led to the original error are also included.

The Source Material

The source material consisted of pooled dog spleens harvested from animals infected by serial passages of distemper virus originally secured from Dunkin and Laidlaw. The strain has been maintained for many years by

* Aided by a grant from the National Foundation for Infantile Paralysis

a biological laboratory engaged in the manufacture of distemper antisera and vaccines Throughout that time it has produced typical responses in both dogs and ferrets as well as antisera capable of controlling canine distemper in the laboratory and in the field Of the thirteen generations of passage virus studied by us seven have been tested in ferrets and three in dogs All have produced the symptoms and lesions of distemper

In brief, canine distemper in the ferret is an acute infectious disease with an incubation period of 4 to 10 days, a duration of 5 to 6 days and a mortality of 90 to 100 per cent The temperature curves are usually biphasic The earliest symptoms are a watery discharge from the eyes and nose followed by reddening and swelling of the footpads As the disease progresses the discharges become purulent, the eyelids are puffed until the eyes are quite closed and the animals become comatose and die

While distemper is more variable in the dog, a uniform disease occurs in carefully selected, healthy animals The incubation, under these circumstances, is said to be quite constant, averaging about 4 days Onset is marked by abrupt fever with watery discharge from eyes and nose, symptoms which are frequently very mild and may easily be overlooked The discharges later become purulent These signs may persist but generally disappear after the first week The dog then refuses food, becomes very weak and difficult to arouse The cases of distemper which appear in the present report all showed such a course

The most characteristic histological criterion of distemper is the appearance of cytoplasmic inclusion bodies of variable size and striking appearance, most constant and numerous in the bile ducts, the epithelium of kidney pelvis and urinary bladder and the trachea and bronchi Our reliance on these inclusions is based on the regularity with which they have occurred in all ferrets showing the classical signs of distemper and their equally regular appearance in dogs examined late in the disease Such inclusions were noted by Dunkin and Laidlaw (3) and Spooner (4)

A portion of our 12th sample of the source material was ground in a mortar with 9 parts of physiological salt solution, centrifuged for 10 minutes at 2000 R P M and the supernatant fluid pipetted off and shown to be bacteriologically sterile Portions of this suspension were injected into mice, guinea pigs, monkeys and a ferret

Mice—Six mice were injected intracerebrally with 0.03 cc. of the original suspension On the 7th day two were found dead in the position illustrated by Traub (5) and three others developed convulsions when suspended by the tail and spun The remaining animals were sacrificed and their brains were harvested A 10 per cent suspension of this tissue injected into a normal ferret produced no clinical response within 14 days when it was sacrificed A suspension of this ferret's spleen was injected into six more mice all of which sickened and died These results and evidence that our mouse colony was free of lymphocytic choriomeningitis are shown in Table I

Guinea Pigs—Three guinea pigs were injected subcutaneously with 0.5 cc. of the same suspension One died the following day The second developed fever on the 4th day

and thereafter failed rapidly. Death occurred on the 9th day accompanied by emaciation and dyspnea. The third pig was also febrile by the 4th day. Temperature remained elevated until the 11th day when death occurred. Emaciation was present, a considerable area of lung was consolidated by a serous pneumonia. The virus present in the brain of this animal has consistently produced the same clinical response in subsequent generations of guinea pigs.

Ferret—One ferret was injected subcutaneously with 0.5 cc of the suspension. Temperature rose to 104.5°F on the 4th day. On the 5th day the temperature was 105.4. On the 7th day it returned to normal to rise again on the 10th day. The animal remained febrile thereafter, soon becoming lethargic and developing severe rhinitis, conjunctivitis, reddened footpads and swollen eyelids. This animal was sacrificed on the 13th day. Conspicuous acidophilic inclusion bodies were present in the bile duct epithelium.

TABLE I
Pathogenicity of Source Material for Mice

Inoculum	Response of mice
12th sample of source material	7 7 (7) (7) (7) H
12th sample after ferret passage (spleen)	2, 3 4 5, 7 11
12th sample after monkey passage (spinal cord)	7 10 (10) (10) (11) (12)
Normal mouse brain	S S S S S S S, S
Normal monkey cord	S S S S S S S, S

0.03 cc of 10 per cent suspensions used. Numerals indicate day of death. Underlining indicates position in death was typical, parentheses that convulsions were observed.

Monkeys—Five monkeys were injected subcutaneously with 0.5 cc of the original suspension. All developed the symptoms we have described (1), approximately 2 weeks of fever followed by several days of subnormal temperature, extreme weakness, diarrhea, emaciation, rhinitis, conjunctivitis and irritability. Two of these monkeys were bled before injection and two others on the 20th day following. None of the sera contained neutralizing antibodies for a known strain of lymphocytic choriomeningitis. One animal was retested 35 days later and its serum found to possess some neutralizing capacity. Another was bled 7 weeks after inoculation and the serum found to completely neutralize the same strain of lymphocytic choriomeningitis virus (Table II).

A third monkey was sacrificed on the 17th day following inoculation. Postmortem examination revealed serous pericarditis, emaciation, purulent rhinitis and conjunctivitis and intranuclear inclusion bodies in the suprarenal cortex. A 10 per cent suspension of the spinal cord of this animal produced the symptoms of choriomeningitis in mice. One mouse was found dead on the 7th day, another on the 10th. Both had the extended legs and arched back often seen in mice dead of choriomeningitis. Two others died during typical convulsions on the 10th day and the remaining two mice on the 11th and 12th days (Table I).

A number of observations which had previously been made indicated that the lymphocytic choriomeningitis virus in the source material was present in considerable amounts.

A 13th sample of the pooled dog spleen was therefore secured and prepared in the usual 10 per cent suspension. Tenfold dilutions of this were made and injected subcutaneously into guinea pigs in 0.25 cc amounts. Equal amounts of each dilution were

TABLE II

Tests for the Presence of Neutralizing Antibodies in the Sera of Monkeys Injected with Source Material

Monkey No	Time serum was collected	Effect in guinea pigs of the injection of virus serum mixtures		
		Test serum	Immune serum	Normal serum
1	Before injection of source material	12, 10, 20	S, S, S,	9, 9, 11
2		10, 10, 19	" " "	" " "

9	10^{-3}	"	102 2	102 9	102 6	S

The immune serum was from a monkey which had lymphocytic choriomeningitis 3 months earlier. Serum had been demonstrated to contain neutralizing antibodies. 0.25 cc of virus suspension and 0.25 cc of serum were mixed and incubated at room temperature for 5 hours and then injected subcutaneously.

mixed with 0.25 cc of dog serum known to possess no neutralizing capacity for Rivers strain of choriomeningitis virus and with the serum of a monkey convalescent from lymphocytic choriomeningitis produced by Rivers' strain of virus 3 months previously. This animal had been shown to be immune and its serum to neutralize virus. The serum suspension mixtures were incubated for 5 hours at room temperature and injected subcutaneously into young guinea pigs. The results are shown in Table III.

Injection of Dogs with Lymphocytic Choriomeningitis Virus

Since no clinical evidence of the choriomeningitis had been recognized in the passage dogs, a number of experiments were planned in which dogs were injected with choriomeningitis virus alone. Two of these experiments are pertinent.

TABLE IV

Tests for the Presence of Neutralizing Antibodies in the Sera of Puppies One of Which Was Injected with Lymphocytic Choriomeningitis

Dog No	Time serum was drawn	Effect in guinea pigs of the injection of virus-serum mixtures		
		Test serum	Immune serum	Normal serum
1	Previous to inoculation	8 9 20	S S, S	7 10 19
2		8, 10 11	" "	" "
1	35 days after inoculation	16, S S	S S S	2, 12 12
2	35 days after inoculation of dog 1	11, S, S	" "	"

Dog 2 was not injected but shared a common pen with No. 1.

Five 3 to 4 months old dogs, raised in isolated quarters, have been injected subcutaneously with lymphocytic choriomeningitis virus. The first experiment consisted of a litter of six cocker spaniel puppies four of which were injected on three occasions, at intervals of 2 weeks twice with 0.5 cc of a 20 per cent suspension of virus recovered from dog spleen by monkey passage and once with 1 cc of blood drawn from a monkey sick with lymphocytic choriomeningitis. None showed clinical response 30 days after the last injection all six were given 1 cc of a 20 per cent suspension of source material. All developed the classical symptoms of canine distemper and died or were sacrificed when moribund. In each animal the cytoplasmic inclusions already referred to were found.

Two mongrel puppies, born and raised in the laboratory, were bled 6 weeks after birth. Their sera tested by the method already described, showed no neutralizing capacity for lymphocytic choriomeningitis virus. 2 weeks after bleeding one of the puppies was injected subcutaneously with 1 cc of a 10 per cent suspension of guinea pig brain known to contain lymphocytic choriomeningitis virus. The two dogs were then placed in a common pen and observed for 10 weeks. The injected dog had a rectal temperature of 104°F on the 14th day. No other evidence of reaction to the injection was

noted The clinical course of the litter mate was uneventful On the 6th, 15th and 33rd days samples of urine were collected from each dog and injected intracerebrally into mice all of which survived The survivors on two occasions were subsequently reinjected with suspensions known to contain lymphocytic choriomeningitis virus and all but one proved susceptible On the 21st day urine was collected and injected subcutaneously into four guinea pigs None developed clinical symptoms or fever and all survived However blood serum taken on the 35th day after inoculation showed the presence of neutralizing antibodies in the sera of both the injected and non-injected dog (Table IV) That this is not due to age is shown by neutralization tests on the sera of eight adult dogs all of which were free of neutralizing antibodies

It appears from the foregoing two experiments that lymphocytic choriomeningitis virus, injected subcutaneously in dogs, produces no recognizable clinical responses although specific antibodies appear in the blood sera 35 days following injection It is also evident and of considerable interest that an injected dog may rapidly transmit the infection to a cage mate

DISCUSSION

The results appear to support two conclusions The presence of two viruses in the source material is indicated by the simultaneous production of distemper in the ferret and a fatal disease in mice and guinea pigs since the latter are not susceptible to distemper (3, 6) The second virus is demonstrated also by passage of the source material in monkeys Thus while distemper may be recovered from the first passage in monkeys (1) later passages are inactive A single mouse passage will produce the same effect The anatomical evidence is also clear since source material is capable of producing both cytoplasmic and intranuclear inclusion bodies in the dog and ferret while passage virus produces only the latter (Table V)

The identification of the second virus as that of lymphocytic choriomeningitis is supported by the clinical and anatomical responses in mice (7), guinea pigs (8), dogs and monkeys (9) and by the demonstration of the appearance, at the proper interval after injection (10) of source material of antibodies capable of neutralizing a known strain of lymphocytic choriomeningitis virus The identity is also shown by the neutralization of source material virus pathogenic for guinea pigs by known immune serum, the demonstration of cross immunity and the occurrence in all the species studied of certain intranuclear inclusion bodies in the suprarenal gland as a consequence both of the injection of source material and known strains of lymphocytic choriomeningitis virus

Thirteen samples of source material have been used during the past $2\frac{1}{2}$ years A brief, chronological summary of the evidence we have indicating that both the virus of canine distemper and that of lymphocytic

TABLE V

choriomeningitis were present throughout that period has been compiled in Table V. Samples 12 and 13 have been described in the present report. Samples 9, 10 and 11 have also been discussed in some detail (2). The evidence of the presence of lymphocytic choriomeningitis virus in the earlier samples rests on the lesions, which have been constant throughout, the demonstration of the virus in passage monkeys by mouse inoculation and cross protection. The evidence for the presence of distemper is entirely anatomical and clinical. After reviewing the evidence in detail, however, the constancy of these criteria and various minor observations strongly support the conclusion that both viruses have been present throughout the entire period.

How lymphocytic choriomeningitis virus was introduced into the passage virus is not known. The dogs and ferrets are not believed to have been exposed to mice or guinea pigs and choriomeningitis virus was not recognized in the laboratories during the period in question. The circumstances responsible for the contamination evidently continue to exist, for another strain of distemper first demonstrated by us to be free of choriomeningitis virus and maintained under similar conditions later was found, in two samples tested, to be similarly contaminated.

It is evident that mixtures of these two viruses may be carried on indefinitely in dogs, for during the period of the present work the material has been passed much more frequently than our sampling would indicate.

One unusual circumstance associated with the source material may be of importance in explaining the continued presence of both viruses. Passage was regularly made with pooled dog spleen suspensions to groups of dogs. Thus the likelihood of losing one of the viruses by the injection of a naturally immune animal was largely avoided and the conditions were unusually favorable to the continued propagation of both.

The demonstration of infective amounts of lymphocytic choriomeningitis virus in the 10^{-2} dilution of dog spleen suggests that an active form of infection was present. This is supported by the presence of inclusion bodies in infected dogs and ferrets, since these are evidently related only to the active phase of infection.

The only clue to the presence of lymphocytic choriomeningitis in the behavior and appearance of the dogs and ferrets injected with the source material has been the presence of intranuclear inclusion bodies in the suprarenal cortex. These have been found in mice, guinea pigs and monkeys as well. Their appearance and occurrence will be described elsewhere.

The absence of clinical manifestations of lymphocytic choriomeningitis

and others the kidney for their carcinogenic action is no less, but probably no more, mysterious than why digitalis selects the heart, morphine the central nervous system or hormones their specific tissues for their actions.

The examples of chemically induced bladder tumors taken together with the older knowledge of bilharzia induced bladder tumors form an opening wedge in the solution of the causes of this type of cancer. A thorough investigation directed toward the discovery of additional possible chemical causes of bladder cancer, keeping in mind the possibility of both exogenous and endogenous carcinogens, appears highly desirable. It might become possible to prevent such tumors by prophylactic measures.

Current Comment

ADMINISTRATION VS. MINISTRATION IN MEDICAL CARE

Legislation transforming the methods of providing medical care has been proposed in Australia, Canada, New Zealand, South Africa and the United States. The discussion of the proposed plans divides into two sharply contrasting streams that may seem to be dealing with wholly different subjects. Politicians, civilian planners, social security officials and propagandists in behalf of collectivization speak and write almost exclusively about the machinery of administration. They are concerned about offices, jobs, the distribution of authority, financial arrangements, political pressure groups and lines of authority. Detailed reports in medical journals of recent discussions by medical associations in all of the countries concerned indicate that physicians are interested primarily in the effects of such plans on the quality of medical service to be rendered. A British physician characterizes this dichotomy of the discussion by saying that political writers and speakers are concerned primarily with "administration," while physicians are interested in "ministration," which, he points out, may be defined as "service."¹ The medical profession is worried about the preservation of the standards of medical education, diagnosis and treatment, maintenance of the type of patient-physician relation that centuries of experience have shown to be most helpful to the sick, and preservation of the initiative, independence and opportunity for research that have been responsible for the marvelous progress of medical science. These are the really important factors in any system of medical practice, certainly all of them will be harmed if placed under political control. To the degree that these essentials of medical practice have been made the responsibility of the medical profession and kept from the control of lay "administrators" have the "ministrations" of medicine grown continuously more effective in the treatment of disease and in the prolongation of human lives.

RH ANTIBODY IN BREAST MILK

The possibility that Rh antibody is given off in breast milk in sufficiently high titer to cause additional blood destruction in Rh positive infants is suggested by data currently reported by Witebsky and his associates¹ of the University of Buffalo. Trace of Rh antibody in second week breast milk of an Rh negative mother who had given birth to an erythroblastotic child was first demonstrated about a year ago by the same authors.² Since then 2 additional cases have been studied in greater detail and at earlier stages after delivery. In the first case the mother, baby and putative father belonged to blood group A. The mother was Rh negative, while both the baby and the father were Rh positive. The mother's serum contained Rh antibody in sufficiently high titer to agglutinate the baby's Rh positive erythrocytes in dilutions as high as 1:256. On the fifth day after delivery (two days after the baby's death) the mother's milk agglutinated Rh positive erythrocytes in dilutions as high as 1:16. Still earlier tests were made with a second erythroblastotic child, in which case the titers of the Rh antibody in the maternal serum and colostrum were the same. This equality suggests that the Rh antibody content of breast milk is at a maximum during the first day after delivery, subsequently decreasing in titer. Assuming that ingested Rh antibodies pass unaltered through the intestinal mucosa to enter the circulation, Witebsky concludes that the colostrum and early breast milk of an Rh negative mother who had given birth to an erythroblastotic child might be a contributory factor in further blood destruction in the Rh positive infant.

REHABILITATION OF THOSE REJECTED FOR MILITARY SERVICE

The selective service registrants who are rejected for military service, especially those who are rejected on neuropsychiatric grounds, constitute a special problem. The state of New Jersey¹ has developed a psychiatric screening plan under the auspices of the selective service system in cooperation with the Department of Institutions and Agencies and with social and health workers throughout the state. This mechanism is designed to collect all the available data bearing on the mental and nervous status and personality of the registrant. Social and health counselors are attached to the local draft boards. A rehabilitation program has been established in cooperation with private as well as public agencies. Following physical and psychologic restoration, young men will be enabled to take their full place in society as citizens and producers. The development of this program together with others of a similar nature will be of help in planning the postwar rehabilitation of many additional men in other areas who will require such assistance.

MEDICINE AND THE WAR

In this section of *The Journal* each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

DEDICATION OF THE ASHBURN GENERAL HOSPITAL

The U S Army Ashburn General Hospital at McKinney Texas was formally dedicated on August 12. Among other speakers on the program were Major Gen Norman T Kirk Surgeon General of the Army, Major Gen Richard Donovan commanding general of the Eighth Service Command, Hon I H Snapp mayor of McKinney, Mr Hanstord Ray president of the local chamber of commerce and Hon Sam Rayburn of Texas speaker of the U S House of Representatives.

The 1,530 bed hospital comprises 110 buildings which occupy a total of 270 acres of land and which are constructed in two parallel rows opening onto a common walkway. The buildings are of tile construction. The hospital was completed at a cost of more than \$3,000,000.

Col James B Anderson M C is the commanding officer and Col Clifford A Gray M C the executive officer. The professional staff as of August 19 was as follows:

MEDICAL SERVICE

Major John Harvey M C chief of the medical service
Major Theodore L Blum M C assistant chief medical service
Capt David M Kidd M C ward officer
Capt Max M Montgomery M C ward officer
Capt Samuel A Radbill M C ward officer
1st Lieut William E Bloomer M C ward officer
1st Lieut Robert A Major M C ward officer
1st Lieut Norman Shafelt M C ward officer

SURGICAL SERVICE

Major Mordecai D Tyson M C chief surgical service
Capt Stirling E Russ M C assistant chief surgical service
Major Samuel L Schenfeld M C ward officer
Major Sidney I Silbar M C chief urology section
Capt Caesar Demko M C ward officer
Capt William C Goodlett M C chief orthopedic section
Capt John M McGowan M C ward officer
Capt Herschal H Pevaroff M C ward officer
1st Lieut John S Gavner M C ward officer
1st Lieut Woodrow W Lovell M C ward officer

EYE, EAR, NOSE AND THROAT

Major Warren M Dodge M C chief E E N T section
Capt Gerson Lowenthal M C assistant chief E E N T section
Capt Fay M Whitsell M C assistant chief E E N T section

LABORATORY

Capt Glenn R Backus M C chief laboratory section
1st Lieut Joseph H Meroid Sn C assistant chief laboratory section
1st Lieut Matthew A Bucca Sn C assistant chief laboratory section

X-RAY SECTION

Capt Robert J Ruby M C chief x-ray section

OUTPATIENT SERVICE

Capt Donald C Merlion M C chief outpatient service

NEUROPSYCHIATRIC SECTION

Major Arthur J Gavigan M C chief neuropsychiatric section

PHYSICAL THERAPY SECTION

1st Lieut Paul M Kistler M C chief physical therapy section

PRISONER OF THE JAPANESE

According to the *Detroit Free Press*, Capt Edward R Neil of the Army Medical Department formerly of Kalamazoo Mich is a prisoner of the Japanese. A card received by his parents in August stating that he was well was the first word from him since the fall of Bataan about seventeen months ago.

LIEUTENANT COLONEL PRATT COMMANDS NEW HOSPITAL IN ENGLAND

A new general hospital in London has been acquired by the United States Army from the British government under reverse lend lease procedure. The building, which was formerly an infants hospital, was redesigned by United States engineers and rebuilt by the British Ministry of Works. It is used mainly for the treatment of emergency cases and minor illnesses and is open to members of the Army and Navy merchant seamen, U S Embassy personnel, Wacs and American Red Cross workers.

The commanding officer is Lieut Col Henry N Pratt of Boston a Harvard graduate and allergy specialist. The executive officer is Major Maurice J Abrams of Brenton Ala a graduate of Johns Hopkins. Major Abrams, formerly an internist on the staff of the University of Maryland, is also chief of medical services. Other department heads are Major Sherwood Russell University of Maine graduate and former surgeon at St John's Mich who is chief of surgical service and Chief Nurse Juanita Bronson, a native of Bucyrus, Ohio and graduate of Grant Hospital Columbus, Ohio.

The hospital is equipped with the latest technical apparatus, mostly of American design, the general hospital equipment, however, is British. There is a dental clinic and an x-ray department, which is in charge of Capt Thomas C Worth of Raleigh, N C. Capt Miles Gullingsrud of Three River Falls Minn sees that army cooks provide a healthful American hospital diet in food rationed England. Eggs, cereal, fresh milk and vegetables are given by the British under reverse lend-lease, and extra eggs and milk are obtainable for special cases. Patients even get ice cream made from evaporated milk and powdered eggs. Cheerful wards are furnished with American adjustable beds and with large leather chairs provided by Britons. Ice boxes taken from blitzed London apartments serve the post exchange.

WACS TO BE ENROLLED IN ARMY-NAVY HOSPITAL SCHOOL

The War Department announced on August 19 that new opportunities have been opened to members of the Women's Army Corps for training and service in the Army Medical Department. Beginning September 10 the first of more than a thousand members of the WAC will be enrolled in the Army-Navy Hospital School Hot Springs Ark, in military hospital training courses. Graduates will be assigned to duty at general and station hospitals. This action is indicative of the opportunities that will present themselves to members of the Women's Army Corps. Each Wac selected to attend the school will be given training in one of five courses. New classes will be started on the tenth day of each month. Three of the courses—those for training x-ray technicians—are of three months duration. For each of these forty-five women will be selected initially. Courses for training medical and surgical technicians are of two months duration for each of which a hundred Wacs will be selected initially. The new field of training now opened to members of the WAC has heretofore been restricted to male military personnel.

AVIATION MEDICAL EXAMINERS

Graduation exercises were held at the School of Aviation Medicine, Randolph Field, Texas, on July 15, following completion of the course for aviation medical examiners. The didactic portion of the course was conducted at Randolph Field, Texas, and the practical portion of the course at the three army air forces classification centers. The list of students graduating follows:

ALABAMA

Charles A. Brumhauer, Captain
Whistler
Joe H. Little, Major, Mobile
Keith W. McPartridge, Major, Tuscaloosa

ARIZONA

Donald Marcus, 1st Lieut., Phoenix
Harry T. Southworth, Captain, Prescott

ARKANSAS

Maurice W. Chastain, 1st Lieut., Bentonville

CALIFORNIA

Dudley Philip Bell, 1st Lieut., Oakland
Samuel C. Benardom, 1st Lieut., Beverly Hills
Robert Vernon Carter, 1st Lieut., Torrance
John G. Clegg, 1st Lieut., Los Angeles
Ralph C. Clevinger, 1st Lieut., Los Angeles
Robert J. Douds, 1st Lieut., Bakersfield
George J. Ferris, 1st Lieut., San Francisco
Lynn Force, Captain, Oakland
David Frost, 1st Lieut., Woodland
William L. Gilmore, 1st Lieut., San Francisco
Edward I. Healey, 1st Lieut., San Francisco
Lloyd B. James, 1st Lieut., Fresno
Harold R. Osander, Captain, Los Angeles (San Marino)
David P. Winkler, Captain, Los Angeles

COLORADO

Gaylor R. Chase, Captain, Denver
Arthur B. Hardy, Captain, Denver
John W. Hewatt Jr., Major, Denver
Joseph H. Lyday, Captain, Denver
Nicholas S. Salibi, Major, Walsenburg
Henry C. Willumsen, Captain, Colorado Springs

CONNECTICUT

Stephen P. Cortes, Captain, Suffield
Harold Ira Harvey, 1st Lieut., New Britain
Edward Martin, 1st Lieut., Rockville
Henry T. Posey, 1st Lieut., New Haven
James S. Walsh, Captain, Bridgeport

DISTRICT OF COLUMBIA

Alexander Halperin, Captain, Washington
Francisco L. Sureda, Lieut. Col. (Uruguayan Officer) Embassy of Uruguay, Washington
Sherman A. Thomas, 1st Lieut., Washington
Redmond B. Walsh, 1st Lieut., Washington

FLORIDA

Charles R. Burbacher, Captain, Coral Gables
William Arnold Christian, Captain, Miami Beach
George H. McSwain, Captain, Arcadia
Efton J. Thoms, 1st Lieut., Miami Beach
Sol C. Werblow, 1st Lieut., Miami Beach
Fred E. Whaley, 1st Lieut., St. Petersburg
Kenneth S. Whitmer, Captain, Miami

IDAHO

John W. Davis, Captain, Glenns Ferry

ILLINOIS

Edward M. Baskerville, Captain, Joliet
Thomas J. Bonick, 1st Lieut., Chicago Heights
Sheldon S. Brownson, Lieut. Col., Rantoul
William H. Delicate, Captain, Edwardsville
Willis G. Disfenbrough, Captain, Chicago
Allan Michel Goldman, Captain, Chicago
Kendall Decatur Gregory, Captain, Decatur
Stanley R. Grudzien, 1st Lieut., Chicago
Joseph H. Kaplan, 1st Lieut., Rialford
Clayton J. Lundy, Major, Chicago
Foster L. McMullan, Major, Chicago
Kenneth J. Malmberg, 1st Lieut., Auburn
Hosmer T. Merrell, 1st Lieut., Chicago
John E. Miller, Captain, Quincy
Joseph M. Mitrick, Captain, Chicago
Milton M. Mosko, Captain, Chicago
William H. Orcutt, Captain, Chicago
Henry J. Parler, 1st Lieut., Chicago
Charles E. Pugh Jr., 1st Lieut., Chicago

MISCELLANEOUS

REHABILITATION SERVICES TO THE
BLIND AND DEAF

Walter E Barton, MD

Major Neuropsychiatry Branch Surgeon General's Office
WASHINGTON D C

Deafness and blindness are deprivations of an essential means of orientation of the normal person. The particular emotional problems of the newly blinded and deafened and their need for assistance in learning how to live without sight and hearing create a need for specialized rehabilitation.

It has been established that it is essential to make an early contact with the handicapped soldier by trained personnel who can encourage him and help him to look forward hopefully to the future. Oftentimes the onset of blindness or deafness is coincident with convalescence from severe medical illness or complicating wounds which will confine a patient in the hospital for a long period of time. Early treatment which restores some of the patient's confidence and optimism will do much to shorten the rehabilitation period. It is the intention of the Medical Department to make available during the period of Army hospitalization a rehabilitation service to all who lose their eyesight or their hearing either here or abroad. The Army does not intend to take over the entire rehabilitation program that is the province of the Veterans Administration for pensionable disabilities or in cases not eligible for veterans benefits of the state vocational rehabilitation services.

The Surgeon General of the Army has designated certain Army hospitals for the care of the blind and the deaf. Valley Forge General Hospital in Phoenixville, Pa. and the Letterman General Hospital in San Francisco have been designated for the care of the blind. Walter Reed General Hospital Washington D C, Hoff General Hospital Santa Barbara Calif. and the Borden General Hospital Chickasha, Okla., have been designated for the care of the deaf.

Well qualified specialists in diseases of the eye and ear and related specialties have been assigned to the designated special

hospitals. In hospitals for the blind, teachers instruct the patient in self care, social adjustment, the use of the talking book, braille reading and writing, the use of braille watches and other techniques used by the blind to compensate for the loss of sight. Occupational therapists teach motor coordination to the blind and the principles of work activity without the aid of sight.

In the hospitals for the deaf lip reading teachers and speech teachers instruct the person how to read lips and to carry on normal social relationships without the aid of hearing. Many of the hard of hearing are helped by hearing aids.

The American Red Cross social worker assists in the transition between the hospital and the home and prepares the family for the reception of the handicapped person. An emotionally upset and overly sympathetic family may through its pity, destroy much of the self confidence and self reliance that the patient will learn unless it is prepared to meet the situation wisely.

It is to be hoped that, if instead of dreary endless days or self pity during convalescence in Army hospitals there are substituted full and busy days of retraining and hopeful anticipation of an interesting future, many soldiers will overcome the handicap of blindness and deafness.

REGISTRANTS WITH POSITIVE
SEROLOGIC REACTIONS

The U S Public Health Service working with state and local health officers, will present to each local board of the Selective Service System through its state director or Selective Service a form (VM 1220) containing the initials of registrants who have been found to have a positive serologic reaction. The local board will fill in certain data on this form and return it through the state director of Selective Service to the local health officer indicated thereon. In due time after the form has been delivered to the local health officer the local board will receive through its state director or Selective Service

another U S Public Health Service form (VM 1222) which again lists the order numbers and initials of registrants having a positive serologic reaction and indicates opposite the order new pertinent data with reference to treatment received by the registrant or his physical fitness for service. The director of the Selective Service System, Lewis B. Heischy, in Local Board Memorandum No 184, issued on July 8, calls special attention to certain columns in form VM 1222 which should be acted on by the local board: (1) needs treatment, (2) now available, (3) probably never available. Director Heischy in this memorandum sets forth the procedure to be used in cooperating with the Public Health Service in making a checkup on registrants with a positive serologic reaction.

HOW HOSPITALS CAN EASE THE NURSING SHORTAGE

According to the American Red Cross, Army nurses are now on duty in 537 stations in the United States and in 28 countries outside the United States: Africa, Alaska, Aruba, Australia, Bermuda, Canada, Egypt, England, the Fiji Islands, Greenland, Hawaii, Iceland, India, Iran, Ireland, Jamaica, Newfoundland, New Caledonia, New Guinea, New Zealand, Pantelleria, Palestine, Panama, Puerto Rico, Philippine Islands, South America (Brazil), Sicily, Trinidad.

Navy nurses are on duty in 212 stations in the United States, including all naval air stations in the interior. They are assigned also to 27 countries outside the continental United States, including Alaska, Hawaii, Puerto Rico, Cuba, the Panama Canal Zone, Australia, Trinidad, the Virgin Islands and many of the islands of the South Pacific. They are at work on the two navy hospital ships *Solace* and *Relief* and will go on duty on the two new hospital ships after they are commissioned.

Nurses of the Army and Navy are flying to distant outposts to bring back wounded soldiers to general hospitals to the rear of the battle fronts or in this country, they are serving on troop transports which fly through enemy infested waters in every part of the globe, they are working in tent hospitals so close to the fighting that a helmet is an essential part of their uniform, they are helping pick up the wounded in the South Pacific who without their ministrations on hospital ships might have died. Courageous and devoted to duty, they are hailed as "good soldiers" in hundreds of hospitals in this global war.

Definite ways in which hospitals can make adjustments so as to ease the nursing shortage and make it possible for more nurses to be released for military duty without endangering life and health of their patients are:

- 1 Increased use of Red Cross Volunteer Nurse's Aides
- 2 Increased use of part time graduate nurses who are not able to give full time, this will mean adjustment to time honored schedules so as to suit the convenience of married women with home responsibilities
- 3 Use of special nurses for critically ill patients only
- 4 Increased use of group nursing so as to allow one special nurse to care for 2 or more patients
- 5 Elimination of all luxury nursing, regardless of the financial status of the patient
- 6 Careful study of nursing practice, so as to limit nurses to the carrying on of professional duties only, thus turning over more duties to nonprofessional aides
- 7 Careful screening of surgical operations so as to include only urgent cases
- 8 Better understanding on the part of hospital management, including board members, that it is their patriotic duty to allow nurses to join the Army or Navy and to put no obstacle in their path
- 9 Adherence to regulations about visiting hours
- 10 Prescribing of certain hours for the delivery of flowers for patients

ANNUAL MEETING OF ASSOCIATION OF MILITARY SURGEONS

The fifty-first annual meeting of the Association of Military Surgeons of the United States will be held at the Bellevue-Stratford Hotel, Philadelphia, October 21-23, under the presidency of Rear Admiral William L. Mann (MC), U S Navy. The program will comprise lectures by officers on active duty, some of whom recently returned from the battle fronts, a practically continuous schedule of motion pictures, scientific and technical exhibits, teaching panels, and entertainment.

Hon. Edward Martin, governor of Pennsylvania, Bernard Samuel, mayor of Philadelphia, and Dr. Eugene Pendergrass, president of the Philadelphia County Medical Association, will give addresses of welcome. Major Gen. Norman T. Kirk, Surgeon General, U S Army, Rear Admiral Ross T. McIntire, Surgeon General, U S Navy, and Dr. Thomas Parran, Surgeon General, U S Public Health Service, will speak. General Kirk will preside at Army Night on Thursday, on which occasion President Roosevelt will greet the assembly by radio and the Chinese ambassador, Dr. Wei Tao-Ming, will give a nationwide radio address. At Navy Night on Friday Rear Admiral McIntire will preside and the Secretary of the Navy, Hon. Frank Knox, will give an address (*THE JOURNAL*, June 12, p 446).

WARTIME GRADUATE MEDICAL MEETINGS

A number of tentative programs of Wartime Graduate Medical Meetings have been previously listed in *THE JOURNAL* (June 5, p 382, July 3, p 683). Two additional tentative programs have now been prepared.

Dr. Frederick A. Collier is national consultant for the six hour schedule on the subject of trauma to the abdomen. This is to include discussions of the pertinent anatomy and physiology, classification of abdominal wounds, treatment of wounds and postoperative treatment including the management of complications.

Urology, with Dr. Herman L. Kretschmer, President-Elect of the American Medical Association, as national consultant, has a tentative program involving four days, each with a six hour teaching schedule. The first day is to include injuries of the genitourinary tract and inflammatory lesions of the genitourinary tract. The second day is to be devoted to the bladder, including stones and tumors. On the third day disorders of the prostate, urethra, scrotum, epididymis and penis are to be discussed. The final six hour teaching schedule, on the fourth day, is to be devoted to the acute retention of urine, the technique of catheterization anuria, and spinal cord bladder following cerebrospinal injuries.

BRAZILIAN OFFICERS OBSERVE METHODS AT FIELD SERVICE SCHOOL

Two Brazilian army medical officers are students in the 34th Officers Training Battalion at Carlisle Barracks, Pennsylvania, observing the methods taught at the Medical Field Service School. They are members of a group of Brazilian officers who are noting army methods in various camps of this country. After this six weeks course is completed they expect to tour another army camp before returning to Brazil.

Capt. Alvaro Menezes Paes graduated from the University of Rio de Janeiro in 1929, then entering private practice until 1935. Capt. Americo Doyle Ferreira also attended the University of Rio de Janeiro, where he received his M.D. degree and engaged in private practice in Recife for a year. Both officers served internships in Rio de Janeiro hospitals.

ARMY-NAVY E

The employees of the W. A. Baum Company, New York, makers of blood pressure apparatus, were awarded the Army-Navy E for achievement in producing necessary war equipment at a ceremony in New York on August 20. Lieut. Col. R. R. Patch of the Sanitary Corps of the Army presented the flag to Mr. W. A. Baum, president of the company, and Capt. Ernest R. Eaton (MC), USNR, presented the E pins to the oldest employee of the company, Mr. H. C. Rasmussen.

ORGANIZATION SECTION

OFFICIAL NOTES

MEDICAL MOTION PICTURES

Medical motion pictures are available on a loan basis from the American Medical Association to medical societies, medical schools, hospitals and other scientific groups. Requests should be instituted as far in advance as possible so that the proper reservations can be made. The exact shipping addresses and dates should be given at the time of the request, also the type of apparatus in which the film is to be run. Responsibility for the projection and care of the film must be borne by the individual or organization which is borrowing it. The American Medical Association does not have projectors available for loan.

The only expense incurred is that of transportation both ways. However, careless handling resulting in serious damage may be charged to the borrower.

Requests should be sent to the Director, Scientific Exhibit, American Medical Association, 535 North Dearborn Street, Chicago 10.

ANESTHESIA

Dynamics of Respiration

Silent, Colored 16 mm, 2 reels, 400 feet each
Running time about 2 minutes
Dynamics of respiration showing normal respiration, respiration in various stages of anesthesia and in different pathologic conditions.
Prepared by the Departments of Anesthesia, Radiology and Photography, University of Wisconsin Medical School, Madison for the Special Exhibit on Anesthesia of the American Medical Association.

Regional Anesthesia for Operations on the Neck

Silent 16 mm, 1 reel, 400 feet
Running time about 16 minutes
Film shows detail of technique of anesthesia for operations on the neck.
Prepared by Dr. Ralph M. Towell, Section on Anesthesia, the Mayo Clinic, Rochester, Minn., for the Special Exhibit on Anesthesia of the American Medical Association.

Signs of Inhalation Anesthesia

Silent 16 mm, 2 reels, 300 feet each
Running time about 25 minutes
Details of signs of inhalation anesthesia with charts presented by Dr. Arthur E. Guedel, Los Angeles.
Prepared by Dr. Henry S. Ruth and Dr. J. Harvey Sigafos, Department of Anesthesia, Hahnemann Hospital, Philadelphia, for the Special Exhibit on Anesthesia of the American Medical Association.

Technic of Blocking Sacral Nerve

Silent 16 mm, 1 reel, 400 feet
Running time about 15 minutes
Film shows details of technique for blocking sacral nerve.
Prepared by the Section on Anesthesia, the Mayo Clinic, Rochester, Minn., for the Special Exhibit on Anesthesia of the American Medical Association.

The Technic of Carbon Dioxide Absorption in Anesthetic Atmospheres

Silent 16 mm, 2 reels, 400 feet each
Running time about 30 minutes
Details of technique for absorbing carbon dioxide in anesthetic atmospheres.
Prepared by Departments of Anesthesia and Photography, University of Wisconsin Medical School, Madison, for the Special Exhibit on Anesthesia of the American Medical Association.

The Role of Carbon Dioxide in Convulsions During Anesthesia

Silent 16 mm, 1 reel, about 200 feet
Running time about 7 minutes
The picture shows convulsions during anesthesia and their control.
Prepared by Departments of Anesthesia, Radiology and Photography, University of Wisconsin Medical School, Madison.

PHYSICAL THERAPY

Aids in Muscle Training

Silent 16 mm, 1 reel, 300 feet
Running time about 12 minutes
Demonstration of ling suspension exercises for the upper and lower extremities, graded exercises on a powdered board for the lower extremities and three kinds of walkers for reeducation exercises.
Prepared by the Council on Physical Therapy, American Medical Association, 535 North Dearborn Street, Chicago.

Contraction of Arteries and Arteriovenous Anastomoses

Silent 16 mm, 1 reel, 250 feet
Running time 10 minutes
This film visualizes the contraction of arteries and arteriovenous anastomoses as seen through a glass chamber installed in a rabbit's ear.
Prepared by Dr. F. K. Clark, University of Pennsylvania School of Medicine, Philadelphia.

Effects of Heat and Cold on the Circulation of the Blood

Silent 16 mm, 1 reel, 300 feet
Running time 12 minutes
Demonstration of the effect of heat and cold on circulation as seen through a glass chamber installed in a rabbit's ear.
Prepared by Dr. F. K. Clark, University of Pennsylvania School of Medicine, Philadelphia.

Effects of Massage on the Circulation of the Blood

Silent 16 mm, 1 reel, 200 feet
Running time 8 minutes
Demonstration of the effect of massage on circulation as seen through a glass chamber installed in a rabbit's ear.
Prepared by Dr. E. R. Clark, University of Pennsylvania School of Medicine, Philadelphia.

Massage

Silent 16 mm, 1 reel, 100 feet
Running time 4 minutes
Demonstration of technique of massage describing the various movements and why they are performed in a given way.
Prepared by the Council on Physical Therapy, American Medical Association, 535 North Dearborn Street, Chicago.

Occupational Therapy

Silent 16 mm, 1 reel, 300 feet
Running time 12 minutes
This film demonstrates occupations that may be prescribed by physicians to motivate and control the desired physical or mental activity of the patient and assist in his adjustment to long hospitalization. A section on cerebral palsy is included, picturing indirect muscle training through prescribed activity and stressing the importance of early treatment to prevent growth of faulty habit patterns.
Prepared by the Council on Physical Therapy, American Medical Association, 535 North Dearborn Street, Chicago.

Underwater Therapy

Silent 16 mm, 1 reel, 400 feet
Running time about 16 minutes
Presentation of therapeutic use of large and small exercise pools, Hubbard tanks and home made tanks and demonstration of types of exercises given in cases such as infantile paralysis, cerebral palsy and postoperative congenital dislocation of the hip.
Prepared by the Council on Physical Therapy, American Medical Association, 535 North Dearborn Street, Chicago.

SYPHILIS

Syphilis—A Motion Picture Clinic (1937)

Sound 16 mm, 4 reels
The four parts may be scheduled separately for successive meetings or all shown at one meeting. The picture provides a complete summary of the present day knowledge of syphilis in all its forms.
Part 1 Diagnosis of Early Syphilis by Dr. John H. Stokes 15 minutes
Part 2 Treatment of Syphilis by Dr. Harold N. Cole 17 minutes
Part 3 Latent and Late Syphilis by Dr. Paul A. O'Leary and Dr. Joseph Earle Moore 21 minutes
Part 4 Syphilis in Pregnancy and Congenital Syphilis by Dr. James R. McCord and Dr. Philip C. Jeans 15 minutes
Sponsored jointly by the American Medical Association and the United States Public Health Service.
Produced by Burton Holmes Films, Inc., 7510 North Highland Avenue, Chicago.

Syphilis—A Teaching Film (1942)

Sound 16 mm, 3 reels
The three parts can be scheduled separately for successive meetings. The picture is an effective presentation of the essentials of the diagnosis and treatment of syphilis from the professional point of view.
Part A Diagnosis of Early Syphilis 18 minutes

Part B Diagnosis of Latent Syphilis, 14 minutes
Part C Management of Syphilis, 29 minutes
Prepared by United States Public Health Service

OTHER SUBJECTS

Blood Transfusion

Silent 16 mm, 1 large reel, 1,200 feet
Running time about 45 minutes
Three methods of blood transfusion illustrated in detail
Sponsored by the Blood Transfusion Betterment Association, 39 East 78th Street, New York
Produced by Mr Joseph P Hachel, New York

Comparative Physiology of Labor

Silent 16 mm, 4 reels, total about 1,400 feet
Running time about one hour
Demonstration of normal labor in the human being, the horse, the cow, the sheep, the dog, the pig and the rabbit
Produced by Prof K de Snoo Obstetric and Veterinary Clinics, University of Utrecht, Netherlands

The Hygiene of Swimming

Silent 16 mm, 1 reel, 400 feet
Running time 15 minutes
This picture shows that man is not adapted to aquatic life and illustrates the danger of infection to the ear, nose and throat, the danger of diving in shallow water and the danger of chilling from cold water
Prepared by Dr H Marshall Taylor, Jacksonville, Fla, for the Section on Laryngology, Otology and Rhinology of the American Medical Association

Medical History in Clinical Teaching

Silent 16 mm, 2 reels, about 300 feet each
Running time about 25 minutes
History of physical diagnosis with scenes from the lives of Hippocrates, William Harvey, Rev Stephen Hales, Leopold Auenbrugger von Auenbrug, Rene Theophile, Hyacinthe Laennec and Wilhelm Konrad Roentgen
Prepared by Department of Cardiology, Woman's Medical College of Pennsylvania, Philadelphia

MEDICAL ECONOMIC ABSTRACTS

DELAWARE MEDICAL CARE PLAN

The Newcastle County Medical Society of Delaware, after a study of various prepayment plans throughout the country, submitted a report outlining a plan to inaugurate a voluntary limited health insurance program. The report was accepted and the plan has now been in operation for about three months. A report of progress by Harold V. Maybee is given in the July issue of the *Delaware State Medical Journal*.

The plan is to cover surgical care only, at least in the beginning. It is operated by the board of trustees of the Group Hospital Service, Inc. Individuals who are also members of the hospitalization plan pay 60 cents a month for the surgical coverage, a family pays \$1.65. At the present time approximately 6,500 are covered by the medical care plan.

The plan operates on the indemnity principle. The physician is to charge the patient the same fee which he would have charged if the patient had not been a member of the Group Hospital Medical Plan. The difference between the total fee charged by the physician and the amount payable under the schedule of indemnification is to be collected by the physician directly from the patient. Participating physicians receive 100 per cent of the schedule of indemnification and nonparticipating physicians receive 50 per cent.

HOSPITAL TO BE OPERATED BY
PREPAYMENT PLAN

The King County (Seattle) Medical Service Corporation has met a hospital emergency by undertaking to cooperate in the construction and operation of a hospital financed largely by the Federal Works Agency.¹ The agency first offered a grant of \$600,000 to construct a wing to the King County Hospital on condition that the county commissioners provide an additional \$200,000. A referendum at the fall election failed to receive the two-thirds majority required for the county expenditures. King County Medical Service Bureau then proposed that the FWA make the grant to the bureau for the purpose of providing for hospital needs.

The King County Medical Service Bureau, organized for the purpose of providing medical service on a monthly prepaid basis for low wage earners, is composed of 480 physicians included in the 665 members of the King County Medical Society. The bureau is operated by the corporate body, the King County Medical Service Corporation, composed of ten members elected by the bureau. Negotiations with the federal officials were conducted by this corporation. The Federal Works Agency made a thorough examination of the bureau and its corporation and became satisfied with its ability to meet requirements for hospital construction.

The Medical Service Bureau has been operated during the past ten years. Its subscribers number about 75,000 employees. It has a daily average of about 80 hospital patients. In addition to caring for this class of patients the hospital will be available for reception of patients of all members of King County Medical Society. It will be operated on a nonprofit basis, any surplus will be devoted to the welfare of its patients.

A 200 bed hospital will be constructed, furnished and equipped, the FWA granting \$600,000 and the Medical Service Corporation supplying the additional \$200,000. The exclusive ownership and operation of the hospital will be vested in the Medical Service Corporation. Dr K. H. Van Norman, who has served as superintendent for the King County Hospital for the past eleven years, will also serve as manager of the new hospital.

MEDICAL SERVICE PLANS IN
NEW YORK CITY

To secure unity in the handling of medical problems in greater New York an economic council has been formed consisting of the chairman and two members of each of the economic committees of the five county medical societies within greater New York. Dr William Bryant Rawls, chairman, outlines the work of this committee.¹ "Some of the more important subjects studied" he says "were (1) the care of the medically indigent, (2) existing voluntary health insurance plans, (3) changing present hospital rules so that physicians may be paid for their services from those ward patients who have medical insurance, and (4) increasing the present compensation rates."

The study of the various voluntary health insurance plans showed that these have not made the expected progress. Out of several plans launched only three were functioning, and these had issued far fewer policies than had been expected. The committee recommended an amalgamation into one plan with a single selling organization. Meetings have been held with all the plans and with the Associated Hospital Service and there are good prospects of a unified plan for greater New York.

The committee has also endeavored to find a means whereby physicians can collect for their services from the ward patients who have medical insurance. Several such patients have entered ward service of the voluntary hospitals and less frequently of the city hospitals. Many of these hospitals have rules that prevent physicians from collecting fees from ward patients even though they have insurance covering medical service. A committee consisting of members of the five county medical societies has been appointed to consult with representatives of the various hospital groups to discuss the possibility of permitting physicians to collect a fee in such cases.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

COLORADO

New Director of Laboratories—William H. Gaub, CPH, U. S. Public Health Service, has been lent to the Colorado State Board of Health to serve as director of the division of laboratories following the resignation of Dr. Frances M. McConnell-Mills, Denver.

Plague in Rodents in Eastern Colorado—On July 5 fleas obtained from black tailed prairie dogs (*Cynomys ludovicianus*) secured in Larimer County 5 miles northwest of Wellington were proved by animal and microscopic examination to be infected with plague. This is said to be the first indication of plague infection in eastern Colorado. According to the state board of health this is the second instance in which plague has been found in Colorado fleas obtained from rodents the other instance being on the western slope. The state board reports no cases of plague in human beings have thus far been recorded in Colorado.

GEORGIA

Personal—Dr. James F. Hackney has been made director of the health department of Atlanta.—J. Allen Scott, associate director of the division of malaria and hookworm service Georgia Department of Public Health, has resigned to become senior statistician of the division of vital statistics of the U. S. Bureau of Census Washington D. C.—Dr. Jacob D. Harris formerly college physician at Eastern Kentucky State Teachers College Richmond now occupies a similar position at Emory University, Atlanta.

Municipal Quarantine Hospital for Venereal Diseases—Federal funds totaling \$250,000 have been allocated to Georgia to finance a new municipal quarantine hospital in Augusta which is expected to be the first community hospital for the treatment of venereal diseases in the nation. Other quarantine hospitals draw their patients from the entire state according to the *Augusta Herald*. Augusta and Richmond County will contribute about \$25,000 to the project. Vocational help will be given to patients while they are receiving treatment for syphilis and gonorrhea. The patients will also be given about \$30 a month so that they will have a fund when a cure has been effected obviating the need to return to vice for a living. The project will take over the NYA buildings at Lake Olmsted, including dormitories, mess hall, recreation rooms and work shops. Forest C. Hunter, P. A. Surg., U. S. P. H. S. (R), has been named in charge of the hospital which was to receive its first patients August 4.

ILLINOIS

License Revoked—The Illinois State Board of Registration in Medicine on June 22 revoked the license to practice medicine of Dr. Delbert R. Blender, Chicago. Dr. Blender was found to be guilty of fraudulent and feloniously carrying on the business of dealing in dispensing and distributing opium and its derivatives without having paid the special tax imposed and without having registered with the collector of internal revenue. The Michigan license of Dr. Blender had been revoked on June 8.

Chicago

City Receives Plaque for Noise Abatement Work—To mark Chicago as winner of the 1943 Achievement Awards of the National Noise Abatement Council, the presentation of a plaque to Mayor Kelly will take place at a special ceremony on September 15. The selection of Chicago as the winner in cities with a population over 500,000 is attributed to the work of the Noise Reduction Council of Greater Chicago of which Mayor Kelly is honorary chairman and Mr. Fred M. Echhoff is president. Memphis was winner in the group of cities with from 250,000 to 500,000. Salt Lake City 100,000 to 250,000 and Charleston W. Va. less than 100,000. The awards are given in recognition of outstanding civic accomplishment in the abatement of unnecessary noise and in the observance of national noise abatement week. In Chicago special emphasis was placed on manpower conservation and programs to aid war production. To consolidate this interest in the health of war workers a special Noise Abatement Commission was created by Mayor Kelly on June 23 with Mr. Echhoff as chairman. Other members of the commission include Dr. Herman A. Bundesen,

Britton I. Budd, Paul Drimalski, Karl Etel, Alderman Joseph S. Gillespie, Alderman William H. Harvey, Patrick H. Joyce, Alderman George D. Kelle, Oscar G. Mayer, Alderman Bertram B. Moss, Alderman Robert C. Quirk, Thomas L. Slater and Philip K. Wrigley. Offices of the new commission are at 134 North LaSalle Street room 1506. Mr. Philip S. English is operating manager. Mr. R. Allen Wilson is secretary of the Noise Reduction Council which was organized in 1941. The two groups will function independently.

INDIANA

Physician Observes Ninety-Ninth Birthday—On August 16 Dr. Henry C. Rogers, Rockville Civil War veteran, observed his ninety-ninth birthday. Dr. Rogers received his degree at the Indiana Medical College, Indianapolis in 1876.

KANSAS

Physician Acts as College President and Practicing Physician—Dr. Orville S. Walters is president of Central College, McPherson, serving in this capacity on week ends, newspapers reported August 4. During the week he serves as house physician at Wesley Hospital, Wichita.

Attorney General Renders Opinion on Hospitals and Narcotics—Applications for registration of hospitals in Kansas may be approved provided the application is executed by a duly qualified physician who will have complete control of and assume responsibility for all narcotic drugs in the hospital according to the Bureau of Narcotics in Washington after an opinion had been handed down by A. B. Mitchell, attorney general of Kansas. The bureau of narcotics points out that applications executed by osteopaths should not be approved as osteopaths in Kansas are not entitled to dispense narcotic drugs.

KENTUCKY

Memorial to the Late Dr. Turner—A public memorial meeting was given by the staff of the T. J. Samson Community Hospital, Glasgow, on July 20 in honor of the late Dr. Caswell C. Turner who at the time of his death on February 28 was president-elect of the Kentucky State Medical Association.

Dr. Blackerby Named State Health Officer—Dr. Philip E. Blackerby, Louisville, assistant commissioner of the state department of health, has been appointed state health commissioner to complete the unexpired term of the late Dr. Arthur T. McCormack. Dr. Blackerby will serve until the next regular election in 1946.

Changes in Health Officers—Dr. Agnes L. Brown, Hardinsburg, has been named health officer of Muhlenberg County.—Dr. James O. Vall, Marion, has resigned as district health officer of Crittenden, Lyon and Caldwell counties to devote his time to private practice.—Dr. William G. Morgan, Owensboro, recently resigned as director of the Daviess County Health Department, to accept a similar position in Montgomery County.—Dr. Chester R. Markwood, Glasgow, has resigned as health officer of Allen, Barren and Monroe counties to engage in private practice at Cave City.

MASSACHUSETTS

New Chairman of Medical Board—Dr. Edward A. Knowlton, Holyoke, was recently elected chairman of the state board of registration in medicine. Dr. Knowlton is now serving his third term as a member of the board. The late Dr. Francis R. Mahony was chairman of the board at the time of his death.

Dr. Cannon Honored—Dr. Walter B. Cannon, Cambridge, president of the recently formed American-Soviet Medical Society, was formally inducted as a member of the Academy of Sciences of the Union of Soviet Socialist Republics at a reception given in his honor by the Soviet embassy on August 12. Dr. Cannon who is professor emeritus of physiology at Harvard Medical School is the first American to be a member of both the Academy of Sciences of the United States and that of the Soviet Union according to the release announcing the honor. The American-Soviet Medical Society was recently organized to stimulate the exchange of medical information between this country and the Soviet Union.

Dr. Clarke Appointed Clinical Professor at Harvard—Dr. Charles Walter Clarke, executive director of the American Social Hygiene Association, New York, has been appointed clinical professor of public health practice at Harvard University. For the past three years Dr. Clarke has served as a lecturer in the Harvard School of Public Health, Boston, on public health administration practice as applied to the control

of syphilis and gonorrhea, giving ten lectures on the subject each year. In the new appointment Dr. Clarke, in addition to teaching, will supervise the field training of the students of public health specializing in venereal disease control. He will continue as executive director of the social hygiene association.

MICHIGAN

State Medical Meeting—The Michigan State Medical Society will hold its seventy-eighth annual session in Detroit at the Statler Hotel, September 22-24, under the presidency of Dr. Howard H. Cummings, Ann Arbor. Out of state speakers will include

- Dr. James E. Paulin, Atlanta, Ga., The Responsibility of the Medical Profession in Postwar Planning
- Dr. Frank H. Lakey, Boston, Biliary Tract Disease
- Dr. Oliver S. Ormsby, Chicago, Avitaminosis in Dermatology and the Value and Limitations of the Sulfa Group in Skin Diseases
- Dr. Edward L. Jenkinson, Chicago, Deformities of the Pyloric Antium Due to Perigastric Adhesions and Bands Simulating Intrinsic Gastric Lesions
- Dr. Paul R. Cannon, Chicago, Protein Metabolism and Resistance to Infection
- Dr. Edward A. Schumann, Philadelphia, Postpartum Sterilization in Indefensible Procedure
- Dr. Irvine McQuarrie, Minneapolis, Causes and Treatment of Edema in Childhood
- Dr. Kellogg Speed, Chicago, Treatment of Open Fractures
- Dr. Harold I. Lillie, Rochester, Minn., Certain Observations on Headaches of Intracranial Origin
- Dr. Everett D. Plass, Iowa City, Wartime Obstetrics
- Col. Leonard G. Rowntree, M. C., A. U. S., Washington, D. C., subject to be announced
- Dr. A. Ashley Weech, Cincinnati, The Challenge of Postwar Pediatrics
- Dr. John C. Whitehorn, Baltimore, Methods of Personality Study in Relation to Medical Problems
- Dr. Hobart A. Reimann, Philadelphia, The Viral Pneumonias
- Dr. William S. Sadler, Chicago, Psychiatric Aspects of the Warring Nations
- Dr. Peter C. Kronfeld, Chicago, Preventable Blindness
- Dr. Harry R. Goerster, Milwaukee, Dermatitis of War Industries in General Practice
- Dr. Walter C. Alvarez, Rochester, Minn., Small Unrecognized Strokes, a Common Cause of Illness in Older Persons
- Drs. Robert D. Mussey, Rochester, and Thomas R. Wilson, co-authors, Abnormal Uterine Bleeding Past Middle Age and Its Management

Wednesday, September 22, designated President's Night, will be a public meeting at which Dr. Schumann, Philadelphia, will present the Andrew P. Biddle Oration on "Medical Education and Present Day Philosophies of Government." On September 24 a special meeting will be held for the public at which Sister Elizabeth Kenny, Minneapolis, will speak. In the afternoon Sister Kenny will discuss "Polomyelitis: Contrast Between the Kenny and Orthodox Concepts, with Results of Treatment." The program will also include sixteen discussion conferences on the specialties. The woman's auxiliary will meet September 20-22.

MINNESOTA

Grants to the University—The University of Minnesota Medical School, Minneapolis, announces a new annual appropriation by the state legislature of \$15,000 to the medical school for special research in the field of cancer. Announcement is also made of the continuation of the grant of \$10,000 a year by the Citizens Aid Society to the medical school in support of cancer research and the program of cancer education and a continuation of the annual gift of \$5,500 by the society to support the George Chase Christian professorship in cancer research. A grant of \$5,000 from the Jane Coffin Childs Memorial Fund for medical research has been made for the support of the work of John J. Bittner, Ph.D., and Dr. Robert G. Green and his associates in the departments of physiology and bacteriology on the nature and mode of action of the milk influence in mammary cancer. A grant of \$3,500 a year for a two year period has been made by the Commonwealth Fund of New York toward the support of the Psychiatric Clinic for Children. Toward the support of this clinic the Stevens Avenue Home of Minneapolis will continue its grant of \$10,000 for the year beginning July 1, 1943. The medical school has accepted a grant of \$3,000 from Parke, Davis & Company to establish a fellowship in clinical hematology in the department of anatomy under the supervision of Hal Downey, Ph.D.

NEW YORK

Lecture on Traumatic Surgery—"Traumatic Surgery with Emphasis on the Treatment of Wounds and Shock" was the title of a lecture by Dr. Walter D. Ludlum Jr., New York, given before the Medical Society of the County of Greene in Catskill, August 27. The lecture was sponsored by the state medical society and the state department of health.

Salary Changes for Mental Hygiene Employees—On October 1 a plan will be made effective in salaries of all mental hygiene employees under provisions of the salary standardization law. Classification of positions for 21,000 employees of

the state department of mental hygiene providing salary increases for many will go far toward providing administration of mental hospitals, the New York Times reported, August 19. In a statement to the press Dr. Frederick MacCurdy, state commissioner of mental hygiene, said that "careful attention was given to gradation of positions so as to augment the possibility of promotion from grade to grade and to make as many career positions as possible in hospitals."

New York City

Changes at New York College of Medicine—Dr. James Leroy Wilson, formerly of Detroit, has been appointed professor of pediatrics and chairman of the department at New York University College of Medicine. New appointments include the following departments of anatomy and psychiatry, Dr. Margaret A. Kennard, New Haven, Conn., assistant professor of anatomy and assistant professor of neuropsychiatry, department of dermatology and syphilology, Drs. Arthur Edward Goldfarb and John Cooper Graham, Brooklyn, assistant clinical professor, department of ophthalmology, Drs. Richard Townley Paton and David Henry Webster, clinical professors, department of psychiatry, Dr. David J. Impastato, assistant clinical professor. Dr. Bernhard Dattner has been promoted to associate clinical professor of neurology, Dr. Frank C. Keil, clinical professor of ophthalmology, Dr. Walter Guernsey Frey Jr., clinical professor of ophthalmology, and Dr. Ervin A. Tusak, clinical professor of ophthalmology.

Physicians Barred in Compensation Cases—Two physicians whose workmen compensation practices were said to be among the largest in the city lost their licenses to do that work on August 11 by order of the state labor department because of fee splitting and other misconduct, the New York Times reports. They are Drs. Emanuel A. Schuffmann and Leo S. Sacharoff. Two other physicians, guilty of similar charges but in lesser degree, had their licenses suspended for six months and three months respectively. Robert H. Feldman and William Philip Smale. The Times stated that 1,200 physicians are under or scheduled for investigation as a result of disclosures concerning "kickbacks" by the recent Moreland Act inquiry into workmen's compensation abuses. The recent 4 cases are the first decisions to be made after departmental trials. Previously Dr. Theodore R. Freedman, Brooklyn, lost his license without formal hearing when he sent a resignation instead of appearing when summoned (THE JOURNAL, July 10, p. 757).

Illegal Practitioner Sentenced to Workhouse—The state education department announces that Frederick Charles Quitzeau pleaded guilty, June 2, to holding himself out unlawfully as a practitioner of medicine and was sentenced on June 16 in the City Court of Special Sessions to serve six months in the workhouse. Quitzeau is said to have a long record of illegal representation. Although he claimed graduation at the Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin Prussia, in 1908, a letter from the school states that "Mr. Charles Quitzeau 'neither studied at this university nor did he receive a degree.'" Before his credentials in Germany were investigated, he was admitted to the medical examinations in Saskatchewan, Canada, Illinois and Maine but failed in all of them, but he is reported to have practiced medicine in these places. In 1922 it was stated that he had been convicted while a member of the Anna (Ill.) State Hospital on a charge of practicing medicine without a license and was fined \$100 and costs. Quitzeau is reported to have been a resident physician in Philadelphia and in Verona, N. J. He was said to represent himself as a physician in Potsdam, N. Y., although one report stated that "he is doing nothing in the way of work." He has applied for staff positions at hospitals and sanatoriums in different sections of the country.

NORTH DAKOTA

Observes Ninety-Third Birthday—Dr. James Grassick, Grand Forks, observed his ninety-third birthday on June 30. Dr. Grassick, who received degrees at Rush Medical College in 1885 and at the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1888, started practice in Burton in 1885.

OHIO

Yellow Fever Volunteer Dies—Lieut. Col. Thomas M. England, for twenty-four years executive officer of the Fifth Service Command Medical Branch, Fort Hayes, Columbus, died on July 23, aged 67. Colonel England was exposed to fomites during the famous Yellow Fever Experiments conducted in Cuba in 1901 by the U. S. Army Commission of which Major Walter Reed was chairman.

Promotions at Western Reserve—Included among recent promotions at Western Reserve University School of Medicine, Cleveland, are

Dr Raymond C. Mehry to associate clinical professor of medicine
Dr William Matthew Champion to assistant clinical professor of obstetrics
Dr Clarence W. Engler to assistant clinical professor of otolaryngology
Alfred H. Tree, Ph.D. to assistant professor of biochemistry
Dr Simon Koletky to assistant professor of pathology
Dr Frederick Robert Mautz to assistant professor of surgery

Personal—Dr Charles A. Dorn, professor of medicine and director of medical research at Ohio State University College of Medicine, Columbus, was recently chosen president of the Ohio Public Health Association.—Dr Lena M. English, resident physician at the Kent State University, Kent, has been appointed associate professor of health and physical education succeeding Dr Elizabeth A. Lengett who resigned to go to Chicago. The latter had held the position since January 1935.—Dr Charles T. Dolezal has been appointed superintendent of the City Hospital, Cleveland, succeeding Mr George P. Bugbee. Dr Dolezal has been city health director since 1942.—Dr Ward D. Coffman, Zanesville, has been appointed chairman of the Ohio State Board of Health, succeeding Mrs. C. T. LaCoste, Toledo.—Dr Sidney J. Heeley, Barton, has been appointed health commissioner of Jefferson County.

SOUTH CAROLINA

Medical Students Campaign Against Wagner Bill—Students at the Medical College of the State of South Carolina, Charleston, adopted a resolution at a meeting August 12 registering their opposition to the Wagner-Murray-Dingell Bill (S 1161). At the meeting the students unanimously backed the stand of the Charleston County Medical Society, which also recently indicated its opposition to the bill. Students at South Carolina proposed to enlist the support of students in the accredited medical colleges of the United States to protest and prevent the passage of the bill, newspapers report.

Changes in Health Officers—Dr Charles E. Billard, Allendale, former health officer for Oconee and Pickens counties, has been appointed health officer for Beaufort County. Dr Edmond J. Bryson, Liberty, former health officer of Greenwood County, will now serve in this capacity in Oconee and Pickens counties, and Dr Mauldin J. Boggs, Jr., Abbeville, health officer of Abbeville and McCormick counties, will also direct the Greenwood county health department until a successor to Dr Bryson is named.—The Sumter County Board of Health is the result of the consolidation of the city of Sumter and Sumter County under the direction of Dr Edward Alex. Heise.—The health departments of Colleton and Hampton counties have been combined into one unit under the direction of Dr Lloyd W. Luttrell, Walterboro.—Dr Charles P. Pope, Jr., health officer of Chesterfield-Marlboro Health District, has been appointed to a similar position in Aiken County.

TEXAS

McReynolds Library Given to Texas University—The medical library of the late Dr John O. McReynolds, Dallas, was donated recently to the University of Texas Medical Branch, Galveston, by Mrs. F. W. Wozencraft, Washington, D. C., daughter of Dr McReynolds. In addition to a large collection of medical books, the gift contains lantern slides, motion picture films and a group of specimens.

Appointments to the Faculty at Baylor—Recent appointments to the faculty of Baylor University College of Medicine, Houston, include the following:

Dr James A. Greene, professor of medicine and chairman of the department and dean of the clinical faculty
Dr Judon L. Taylor, professor and chairman of the department of surgery
Dr Herman W. Johnson, professor of obstetrics and chairman of the department
Dr James H. Park, Jr., professor of pediatrics and chairman of the department
Dr Ernst W. Bertner, professor of gynecology and chairman of the department
Dr James Greenwood, professor and chairman of the department of neuropsychiatry
Dr Culver M. Griswold, professor and chairman of the department of dermatology and syphilology
Dr Everett L. Bohr, professor and chairman of the department of ophthalmology
Dr Claude C. Cody, Jr., chairman of the department of otolaryngology
Dr Joseph B. Foster, professor of orthopedic surgery and chairman of the department
Dr Herbert T. Hayes, professor of proctology and chairman of the department
Dr John M. Tribble, professor of urology and chairman of the department
Dr Stuart Anderson Peoples of the University of Alabama School of Medicine, University professor of pharmacology

VERMONT

Rehabilitation Program for Tuberculous—The trustees of the Vermont Tuberculosis Association have appropriated \$3,000 which will be matched by federal funds to establish a special rehabilitation program for the tuberculous in the state. The money will be expended under the supervision of the committee on rehabilitation of the association in consultation with the rehabilitation division of the state department of education and physicians in the state sanatoriums.

GENERAL

Bar Association Opposes Medical Control by Government—The American Bar Association at its sixty-sixth annual meeting at the Drake Hotel, Chicago, August 26, approved a resolution opposing any legislation now before Congress which seeks to establish federal control of the medical profession and the regimentation of doctors and hospitals, newspapers report.

New Medical Director of Nursing Service—Dr James M. Fraser, formerly of Lawton, Okla., has been appointed medical director of the Frontier Nursing Service, effective August 21. He succeeds Dr John H. Gooser, Hyden, Ky., who has joined the armed services. Dr Fraser graduated at George Washington University School of Medicine, Washington, D. C., in 1939.

American Home Products Acquires Gilliland Laboratories—The American Home Products Corporation announces the acquisition of Gilliland Laboratories, Inc., of Marietta, Pa., producer and distributor of serums, vaccines and antitoxins. The management of the laboratories will remain unchanged but its production and sales will round out the lines of pharmaceuticals and biologic products now marketed by John W. Wetli and Brother, Inc., Reichel Laboratories, Inc., and Ayerst, McKenna & Harrison.

Annual Mississippi Valley Meeting—The ninth annual session of the Mississippi Valley Medical Society will be held at the Hotel Lincoln-Douglas, Quincy, Ill., September 29-30. Among the speakers will be

Dr Warren H. Cole, Chicago, Treatment of Toxic Gaster
Capt. Henry L. Dollard (MC), U. S. Navy, Tasks of the Medical Department of the U. S. Navy in Global War
Dr Norris J. Heckel, Chicago, Cystitis: Causes and Treatment
Dr Robert W. Keeton, Chicago, Treatment of Patients with Toxic Hepatitis
Dr Paul B. Magnuson, Chicago, The Misused and Misinterpreted Intervertebral Disk
Dr Raymond W. McNeal, Chicago, Cancer of the Large Bowel
Dr Carl M. Peterson, Secretary of the Council on Industrial Health of the American Medical Association, Industry Needs the Physician
Dr Charles H. Pfister, Chicago, Accomplishments and Difficulties Encountered by Procurement and Assignment Service
Dr Malcolm M. Cook, St. Louis, Rabies from the Practitioner's Point of View
Dr Willis M. Fowler, Iowa City, Diagnosis and Treatment of the Common Anemias
Dr Rutherford B. H. Gradwohl, St. Louis, Facts About Rh Agglutination
Lieut. Comdr. Paul W. Greeley (MC), U. S. Naval Reserve, Some Personal Experiences in Current Military Plastic Surgery
Dr Samuel F. Haines, Rochester, Minn., Treatment of Parathyroid Insufficiency
Dr Joseph V. Herzog, Milwaukee, Office Procedures in Minor Rectal Pathology
Dr Archibald L. Hovne, Chicago, Improved Methods in Treatment of Meningitis
Dr Julius Jensen, St. Louis, Cardiology
Dr John de J. Pemberton, Rochester, Some Problems in the Surgical Management of Carcinoma of the Colon and Rectum
Dr George J. Rukstien, Chicago, Clinicopathologic Conference
Dr Leroy Hendrick, Sloan, Chicago, Vertigo and Common Associations
Dr Thomas Bell, William, Mount Vernon, Ill., Importance of Good Prenatal Care in Obstetrics

On Thursday evening, September 30, the speakers will be Brig. Gen. Fred W. Rankin, M. C. U. S. Army; Dr George W. Post, Chicago; Dr Andrew W. McAlester, Kansas City, Mo.; and Dr Edward M. Myers, Woodward, Iowa. Additional information may be obtained from the secretary, Dr Harold Swanberg, Quincy.

Leprosy Study for Latin American Physicians—In cooperation with the Office of the Coordinator of Inter-American Affairs and the U. S. Public Health Service, the Leonard Wood Memorial has undertaken a program of study for eight Latin American physicians who are especially interested in leprosy. The program, which opened on June 1 for a period of one year, will be divided as follows: the National Leprosarium, the U. S. Marine Hospital at Carville, La., for instruction by the regular staff and special consultant in various phases of leprosy; Western Reserve University for epidemiology, pathology and dermatology; the University of Michigan for bacteriology; Tulane University of Louisiana School of Medicine and Louisiana State University School of Medicine, New Orleans, for parasitology, hematology and

physical diagnosis and epidemiology. Before returning to their respective countries the physicians will visit various American cities to observe methods of medical, hospital and public health services. The physicians were guests of Perry Burgess, president of the Leonard Wood Memorial, at his home at Erie Vista, Geneva on the Lake, Ohio, from August 6 to 15, during which time several conferences on leprosy were held. The visitors are:

Dr. Alberto Caballero Villaveces, Colombia, assistant doctor of the National Hospital of San Juan de Dios.

Dr. Luis Rendon Ch, Ecuador, director del Leprosario Nacional de "Veideruz".

Dr. Augusto Rodolfo Merera, Argentina, head of clinic of leprosy service, assistant physician in chair of dermatology.

Dr. Rafael Cepeda R, Colombia, medical director of the "Hospital of Loro".

Dr. Eduardo Carhom, Argentina, head of dependents section of the leprosy service, Hospital Carrasco, Rosario, assistant physician to the chair of dermatology, physician of department of prophylaxis and anti venereal diseases, head of dermatology service to primary schools of Rosario, consulting physician of "Hospital de Leprosos," Rosario.

Dr. Artur Porto Marques, Brazil, assistant of the Instituto Evandro Chagas, Belém, Pará, Brazil.

Dr. Glauco Leite Rocha, Brazil, physician under contract in the National Service of Leprosy, Public Health Department, assistant at the dermatologic clinic of the University of Brazil.

Dr. Roberto Nunez Andrade, Mexico, medical officer in the Office of Prophylaxis of Leprosy in the federal department of health, dermatologist, department of welfare, professor of dermatology, National School of Biological Sciences of the National Polytechnic Institute, chief of dermatology clinic in the National School of Medicine.

Mr. Burgess was to be appointed consultant to the Secretary of War on epidemic diseases in a new project of assistance of the memorial to the Surgeon General of the U. S. Army. Dr. Norman C. Kieffer, Geneva, has been appointed medical assistant to Mr. Burgess in his capacity as president of the memorial. He is engaged in research on leprosy. He graduated at the University of Michigan School of Medicine, Ann Arbor, in 1930 and is director of internal medicine and diagnostic laboratories of the A. S. Hickok Memorial Hospital, Geneva.

HAWAII

Epidemic of Dengue Fever—An epidemic of dengue fever in Honolulu, originating in the Waikiki Beach area, has become citywide with 39 cases reported, and on August 14 the Army barred military personnel from six more residential districts, newspapers announce. The Army Chemical Warfare Service is spraying insecticide in homes where cases are reported. The city's seven thousand air raid wardens are conducting a house to house check to eradicate breeding places of dengue carrying mosquitoes.

LATIN AMERICA

New Medical School Building—The Faculty of Medical Sciences of Buenos Aires recently opened its new building, occupying one whole block on Paraguay, Junin, Charcos and J. E. Uriburu streets. It consists of twenty floors and will house the faculties of medicine, biochemistry, pharmacology, odontology, the Institute of Pathologic Anatomy, the Pardo Maternity and the Pavilion for tubercular patients.

Health Activities in Latin America—The increasing development of Latin American health activities is reflected in the brief accounts in the Newsletter of the Health and Sanitation Division of the Coordinator of Inter-American Affairs.

Construction—New building projects constitute a major development in practically all of the republics. In Colombia this includes new hospitals in Antioquia, Zaragosa and Remedios and health centers in Magdalena, the Choco, La Guajira, Buenaventura. In El Salvador health centers are being planned for Santa Ana, San Salvador and Santa Tecla. The construction and equipment of a diet kitchen at the Public Health Nursing School was completed at Port-au-Prince, Haiti.

Veneral Disease—A clinic is to be established at Comito, Nicaragua, a naval base, to carry out a program of registration and periodic examination of prostitutes. Women found infected are to be placed in the venereal disease hospital at Managua until rendered noninfectious.

Health Education—Four physicians from El Salvador left for the United States in June for special work. Dr. Jose Francisco Valiente for tuberculosis control study, first at Saranac Lake Sanatorium and then at other sanatoriums, Dr. Alberto Aguilar Rivas, to work for a degree of master of public health at the Johns Hopkins School of Hygiene and Public Health, Baltimore, and Drs. Victor Manuel Posada and Roberto Masferrer Pineda for study at the Johns Hopkins University School of Medicine for training as instructors in the National Medical School at El Salvador. In Guatemala,

where the largest cinchona plantation in the Western Hemisphere is being developed (THE JOURNAL, June 12, p. 457) on a plantation known as "El Porvenir," the Servicio is working out a medical care program for the 3,000 laborers to be employed there. The work will include personal instruction, the furnishing of facilities for water supply, sewerage and other sanitary needs, new construction for living quarters and the installation of sanitary facilities for both new and old buildings.

Malaria—Particular attention has been directed to malaria, an outbreak of which occurred in May in Buenavista, Colombia, involving more than 182 cases. In El Salvador, after a survey, laborers found with malaria parasites were treated by the National Department of Health. Special control measures have been instituted in San Miguel, Sonsonate and Acajutla, in Puerto Barrios, Guatemala, plans have been drawn to eliminate mosquito breeding places permanently in the El Confral and La Montanita swamps. At Port-au-Prince, the Pan American Airways has contributed \$4,000 to defray partly the cost of installing a concrete masonry sewer. In Nicaragua Drs. Leonard S. Rosenfeld, M. A. Sanchez-Vigil and Mr. Ramiro Sanchez of the National Institute of Hygiene visited Esteli to study the sources of anopheline malaria vectors in the city and in the nearby road camp of Pan American Highway contractors.

FOREIGN

New Scientific Films—"War Medicine on the Western Front," the latest film produced by Vladimir Karin and Nikolai Bodanov, shows the modern Russian science of war medicine, the problems confronting the medical service at the front, and methods of treatment and evacuation of wounded. According to the *Information Bulletin*, Embassy of U. S. S. R., four studios in the Soviet Union "are producing scientific and technical films and popular science subjects, with a total of 120 releases annually." Among these is a series "Ready for Air and Chemical Defense."

Research in Industrial Medicine—The British Medical Research Council has arranged with the London Hospital for the establishment there of a department for research in industrial medicine, *Science* reports. Dr. Donald Hunter, physician to the hospital, has accepted a part time appointment to the staff of the council as physician in charge of the department, the council has appointed Drs. Kenneth Perry and Norman Spoor as research assistants. The hospital will be responsible for the treatment of cases under investigation. The department will undertake clinical research into disorders affecting industrial workers. The staff will also study such problems in other parts of the country. The department will also be responsible for teaching in the subject. The new arrangement supersedes one made last year for the appointment of a full time director of research in industrial medicine attached to the council's headquarters. The position had become vacant through the appointment of Dr. A. W. M. Ellis to the regius chair of medicine at the University of Oxford.

CORRECTION

"Hemolytic Syndromes"—In the review of this book (by Dr. William Dameshek and others, published by H. Jackson Company, P. O. Box 122, Essex Station, Boston), published in THE JOURNAL, July 31, the price was quoted at \$1.50. Owing to increased printing costs for the second edition the present price is \$2.25 per copy prepaid.

Government Services

Physicians Needed at St. Elizabeths Hospital

The U. S. Civil Service Commission announces that a number of junior medical officers are needed at St. Elizabeths Hospital, Washington. It is possible that women may be utilized in these positions, the appointments to be made as vacancies arise. The positions pay \$2,000 a year plus \$433 overtime pay. There is no age limit. According to the announcement there are fine opportunities for psychiatric residencies, and rotating internships are open to recent graduates of medical schools. Additional information may be obtained from the U. S. Civil Service Commission at Washington, first or second class offices and civil service regional offices.

The Detection of Pulmonary Tuberculosis in Women

Mass radiography is being used on a large scale for the early detection of pulmonary tuberculosis. F Temple Clive has given in *Tubercle* a review of the radiography of 30,000 women recruits for the Women's Auxiliary Air Force. The cases are to some extent selective, as every woman had previously been examined at a national service medical board. The youngest was 17½ years of age and the oldest 45. All were practically symptomless and those noted as having any symptoms admitted to their presence only after detailed history taking. All the women were on full duty, which included marching and physical training yet this strenuous exercise did not give any patient cause to suspect that she was not perfectly well. The value of this new method of examination is shown by the fact that 102 cases of active tuberculosis were found. Calcified nodules and/or glands were seen in 286 cases. The absence of admitted symptoms was remarkable. After close questioning only 29 of the acutely involved admitted symptoms, chiefly lassitude, loss of weight and cough, in that order. Even 4 women with advanced tuberculosis were unaware of any symptoms although the prognosis was only a matter of weeks. In no less than 64 cases no significant history of any kind was obtained. In spite of the complete absence of symptoms almost half the cases had already passed beyond the early (or group 1) stage. Cavitation was present in 16 unilateral and 4 bilateral cases. Thus 20 patients required urgently admission to an institution for collapse therapy. Abnormal physical signs were found in the chest in 66 cases. This figure includes only cases in which signs were so definite that they should be discovered by physicians not specially trained in chest work and without x-ray aid. The sputum was positive in 18 cases, negative in 33 and entirely absent in no fewer than 51 (exactly half the active cases). These figures may be to some extent fallacious as women tend to conceal that they have any sputum and in spite of advice are averse to expectoration. Clubbing of the fingers occurred in 12 cases in 3 of which it was the only abnormal sign. In 136 cases inactive pulmonary tuberculosis was found. This is a percentage of 0.45. The 102 active cases give a percentage of 0.34. These percentages may be compared with those for male recruits to the Air Force which were 0.22 and 0.36 respectively. Thus the total percentage for the women was 0.79 and for the men 0.58. Below the age of 20, active tuberculosis was found twice as common in women as in men and inactive tuberculosis thrice as common.

The Lessons of Wartime Feeding

Lord Horder the president in addressing the Food Education Society on the subject *Lessons Taught by Wartime Feeding* said that the war had found science just ready for a great acceleration in the study of nutrition. Science had gained much from being given a definite brief particularly through the amount of field work provided by wartime conditions. The two most essential foods—bread and milk—were the chief subjects of controversy. The bread situation had settled down with a compromise between extremists—those who pressed for wholemeal and those who hankered after white bread. It was

the policy of the society to teach the virtues of wholemeal bread and it would press the government to encourage in every way its nationwide adoption. It would take possibly a decade to get absolutely clean milk, and steps toward that aim must be regarded as a long term policy. Pasteurization was the short term policy, for it destroyed the germs and left the food value untouched. Yet the government still hesitated to enforce pasteurization. If the machinery was not available, could not some steel be released for the preservation of life?

New Fellows of the Royal Society Whose Work Is of Medical Importance

The fellowship of the Royal Society (F.R.S.) is the highest scientific honor attainable in the country. It is conferred only on those who have done important original scientific work. In the recent list of new fellows are the following whose work is medical or of medical interest.

Prof P. A. Buxton, director of the Department of Entomology, London School of Tropical Medicine. Distinguished for research in medical entomology with special reference to conditions under which insects responsible for the transmission of diseases multiply and the measures of control.

Ivan de Burgh Daly, professor of physiology in the University of Edinburgh. Distinguished as an originator of essential items of modern physiologic technique and for important contributions to the physiology of the circulation in the lungs and bronchial tubes.

Dr A. J. Evans, director of research at May & Baker (manufacturing chemists at whose works sulfapyridine and other drugs have been originated). He is distinguished for his chemical and biochemical research. His work in organizing an industrial research laboratory has led to some of the most important synthetic remedies in recent years.

Alexander Fleming, professor of bacteriology, St. Mary's Hospital. Distinguished for his contributions to bacteriology, immunology and chemotherapy.

G. A. R. Kon, research professor of chemistry at the Royal Cancer Hospital. Distinguished for researches in organic chemistry. His work on the polyterpenes has provided a basis for a number of important developments.

Prof Wilder Penfield, director of Montreal Neurological Institute. Distinguished for his researches in neurohistology and as a neurosurgeon.

Success of Immunization Against Diphtheria

The Ministry of Health reports remarkably good results from immunization of children against diphtheria, which is now performed on a large scale in this country. In the county districts of Northamptonshire over 36,250 children under the age of 15 have been immunized since 1941. During that period only 1 of these children contracted the disease, and the attack was not so severe as to prove fatal. On the other hand among over 19,400 children in the same county districts who had not been immunized there were 101 cases of diphtheria with 15 deaths. Among 8,000 children under the age of 5 years who had been immunized not a single case of diphtheria occurred while among 9,200 children under 5 who had not been immunized there were 36 cases with 11 deaths.

The Ministry of Health also states that 46 per cent of children under the age of 5 have now been immunized in county districts of Northants and 71 per cent of those between 5 and 15 years. The percentage for all ages up to 15 is 65. The ministry is carrying on a campaign to secure the immunization of at least 75 per cent of the child population of the country.

PROPERTY OF THE
FEDERAL GOVERNMENT

Edward B Nelson ☉ Spokane, Wash., Medical Department of Tulane University of Louisiana, New Orleans, 1895, past president of the Spokane County Medical Society, aged 73, on the staff of the Deaconess Hospital, where he died, June 18, of arteriosclerotic hypertensive heart disease

William Payne Nichols, Bloomfield, Ky., Hospital College of Medicine, Louisville, Ky., 1903, aged 62, died, June 26, of peptic ulcer

Albert O'Bannon, Okeechobee, Fla., American Medical College, St Louis, 1911, aged 69, died, June 13, of cerebral hemorrhage

John Francis O'Brien, Fall River, Mass., McGill University Faculty of Medicine, Montreal, Que., Canada, 1910, member of the Massachusetts Medical Society, police surgeon, on the staff of St Anne's Hospital, aged 57, died, June 11, of tumor of the kidney

Amos Cameron Olmsted ☉ Wells, Nev., Cooper Medical College, San Francisco, 1895, past president of the Nevada State Medical Association and the Nevada State Board of Medical Examiners, past president and secretary of the Elko County Medical Society, member of the board of education and county health officer, on the staff of the Elko General Hospital for ten years had been regent of the University of Nevada, Reno, aged 71, died, June 14, of uremia and nephrolithiasis

Meade B Owens ☉ Newport, Ark., Gate City Medical College, Texarkana, Ark., 1903, served as health officer of Jackson County, aged 70, died, June 20, of arthritis

Alfonso Maria Padilla, Youngstown, Ohio, Jefferson Medical College of Philadelphia, 1914, aged 53, died, June 16, of heart disease

Carl Pangerl, Muskegon Heights, Mich., Chicago College of Medicine and Surgery, 1917, member of the Michigan State Medical Society, aged 49, on the staffs of the Mercy Hospital and the Hackley Hospital, Muskegon, where he died, June 13, of lobar pneumonia

Dorsey C Peck ☉ Grafton, W Va., Louisville (Ky) Medical College, 1905, aged 65, died, June 15, of carcinoma

William Marcus Petersen, Chicago, Milwaukee Medical College, 1902, also a pharmacist, member of the staff of the Lutheran Deaconess Home and Hospital, aged 67, died, June 23, of cerebral hemorrhage, chronic nephritis, chronic myocarditis and coronary occlusion

Sterling Blackwell Pierce, Weldon, N C., Bellevue Hospital Medical College, New York, 1897, aged 69, died, June 23, in the Duke Hospital, Durham, of septicemia

William Arthur Pike, Ottawa, Ill., Rush Medical College, Chicago, 1896, formerly a member of the Illinois National Guard, veteran of the Spanish-American War, at one time city health officer, aged 69, died, June 25, in the Elgin (Ill) State Hospital of hypertension and arteriosclerosis

Frank E Piner, Denton, Texas, Medical Department of Tulane University of Louisiana, New Orleans, 1894, past president and secretary of the Denton County Medical Society, member of the State Medical Association of Texas, health officer of Denton, aged 73, died in the Denton Hospital and Clinic, June 30, of malignancy of the gastrointestinal tract

Harry Thomas Prideaux ☉ Cresson, Pa. Medico-Chirurgical College of Philadelphia, 1908, member of the staff of the Mercy Hospital, Altoona, physician for the Pennsylvania Railroad Company and the Pennsylvania Coal and Coke Corporation, medical member of the civilian defense council of Cresson, aged 64, died, June 12, of coronary thrombosis

James R Rankin, Muncy, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1883, member of the Medical Society of the State of Pennsylvania, a member and president of the board of health of Muncy, served during World War I, aged 82, died, June 21, in the Williamsport (Pa) Hospital of aneurysm

Hyman Rapaport ☉ Los Angeles, University of Pittsburgh School of Medicine, 1919, assistant clinical professor of medicine at the University of Southern California School of Medicine, specialist certified by the American Board of Internal Medicine, on the staffs of the Cedars of Lebanon and the Los Angeles County General hospitals, aged 50, died, June 16, of coronary thrombosis

Frederick Edward Rehfeldt ☉ Jackson, Miss., University of Nashville (Tenn) Medical Department, 1904, member of the Southeastern Surgical Congress, member of the Selective Service System, for many years physician for the fire department, member of the staffs of the Mississippi Baptist Hospital and the Jackson Infirmary, where he died, June 8, of leukemia, aged 62

Ellsworth Milton Tench ☉ Buffalo, University of Buffalo School of Medicine, 1917, consulting proctologist to the J N Adam Memorial Hospital, Perrysburg, aged 54, died, June 1, of cerebral thrombosis, hemiplegia, arteriosclerosis and hypertension

Charles Wesley Thomas, Warren, Ohio, Western Reserve University Medical Department, Cleveland, 1903, member of the Ohio Medical Association, for many years chief surgeon for the Republic Steel Corporation, aged 66, died, May 17, in the University Hospital, Cleveland, of postoperative hemorrhage and benign enlargement of the prostate gland

Frank Colfax Thornburgh, Alma, Mich., Homeopathic Medical College of Missouri, St Louis, 1904, on the staff of the R B Smith Memorial Hospital, aged 74, died, June 13, in the Saginaw (Mich) General Hospital of chronic uremia and hypertrophy of the prostate

Frank L Thornburgh, Middletown, Ind., Medical College of Ohio, Cincinnati, 1878, aged 86, died, June 7, in Fort Wayne of cardiovascular renal disease

William W Tindall ☉ Shelbyville, Ind., Eclectic Medical Institute, Cincinnati, 1903, past president of the Shelby County Medical Society, examining physician for the county draft board during World War I and served in the same capacity recently, aged 66, died, June 18, of heart disease

Andrew Jackson Turner, Beeville, Texas, Memphis (Tenn) Hospital Medical College, 1901, member of the State Medical Association of Texas, for several terms president of the Bee-Live Oak-McMullen Counties Medical Society, for the past twenty-five years health officer of Beeville, served as a first lieutenant in the medical corps of the U S Army during World War I, on the staff of the Beeville Hospital, aged 71, died recently of coronary thrombosis

Benjamin Franklin Underwood, Louisville, Ky., Southwestern Homeopathic Medical College and Hospital, Louisville, 1910, member of the Kentucky State Medical Association, aged 57, died, June 7, in the Methodist Deaconess Hospital of cerebral hemorrhage

Alan P Vaughan, Arcade, N Y., University of Buffalo School of Medicine, 1896, member of the Medical Society of the State of New York, formerly health officer and school physician, aged 73, died, June 1, in the Buffalo General Hospital of carcinoma of the prostate, coronary heart disease and Laennec's cirrhosis

William Henry Wilson, Orlando, Fla., College of Physicians and Surgeons, Boston, 1903, at one time on the staff of the Worcester (Mass) City Hospital, aged 76, died, June 9, in the Florida State Hospital, Chattahoochee, of pneumonia

James R Wolfenden, Chicago, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897, aged 70, died, June 11, of chronic myocarditis

Allen Henry Wright ☉ Northfield, Mass., University of Maryland School of Medicine, Baltimore, 1906, member of the New England Society of Psychiatry, served as president of the Franklin District Medical Society, on the staffs of the Farren Memorial Hospital, Montague, Brattleboro (Vt) Memorial Hospital and the Franklin County Public Hospital, Greenfield, aged 65, died, June 17, of cardiorenal disease

George Wesley Younkin, Mason City, Iowa, State University of Iowa College of Medicine, Iowa City, 1876, formerly a minister, aged 96, died, May 16, of myocardial insufficiency

KILLED WHILE IN MILITARY SERVICE

Ralph Robert Nix ☉ Passed Assistant Surgeon, U S Public Health Service, Springfield, Mass., Louisiana State University School of Medicine, New Orleans, 1941, commissioned assistant surgeon in the reserve corps, U S Public Health Service, June 10, 1942, assigned to U S Marine Hospital, Mobile Ala, commissioned assistant surgeon in the regular corps, July 20, 1942, assigned as medical officer aboard Coast Guard Cutter *Escanaba*, Dec 17, 1942, recommended for special commendation because of excellent services performed in rescue work of survivors of the S S *Dorchester*, promoted to grade of passed assistant surgeon, May 1, 1943, aged 26, killed at sea, June 14, when the *Escanaba* was destroyed following an 'explosion of undetermined cause'

PREDICTION OF POLIOMYELITIS CASES IN EPIDEMIC YEARS

To the Editor—Plotting the weekly trend of poliomyelitis in Chicago for the two highest years on record—1917 and 1937—revealed an interesting phenomenon common to the two years.

Histograms of the cases reported each week in these two years as well as that of 1943 are shown in chart 1. The cases

Chart 1—Poliomyelitis morbidity, Chicago. Cases reported weekly, July-December 1940-43, 1917 and 1917.

in the first six months are not shown as they were negligible. The trend starts up slowly for the first few weeks then rapidly gathers momentum as the slope changes from a horizontal to a vertical position on the way down from the peak the picture is almost duplicated.

Since case reports are likely to come in irregularly a curve smoothed by three week moving averages was used in chart 2. The symmetry of the 1917 and 1937 curves is immediately apparent.

The resemblance to a normal curve even to the asymptotic tails on both ends is remarkable. Also included in the chart are three recent years that did not stand out as epidemic years. Even with three week moving averages the values although suggestive of a normal curve, were irregular. However the probable explanation is that in high years when the public is conscious of the disease there is a likelihood of an almost complete reporting of the cases whereas in off years mild forms are not so apt to be reported.

The tendency for the disease course to approximate the normal curve in its entirety offers the possibility of predicting in the early part of the season the complete picture for the year with a foreknowledge of weekly estimates the peak week and a good estimate of the total cases.

According to the curve the peak this year should occur the week of September 4. This can be done by noting from chart 2 that whenever the slope rises sharply it will continue so for five or six weeks and then repeat the same values on the way down. When the slope does not change rapidly as is seen for 1940, 1941 and 1942 the peak week has a low total and the total cases for the year is correspondingly low.

Chart 2—Poliomyelitis morbidity, Chicago. Three week moving average, July to December 1917, 1937 and 1940-43.

Is there a hint from this evidence as to the nature of the disease itself? If a constant force should be exerted on a group and at a certain time of the year for some reason that group lost some of its power to resist that force a graph of the number of individuals bending under it would describe a normal curve.

Another method of approach which may be more fruitful in predictive possibilities is the plotting of the cumulative weekly data on a logistic curve. This is being given study.

REVIEW OF DISEASES OF THE BREAST BY CHARLES GESCHICKTER

To the Editor—In your issue of July 17 you printed a book review of *Diseases of the Breast* published by the J. B. Lippincott Company.

The review is a departure from acceptable standards of printed comments of this nature in many respects. In the first place, being published in the official journal of the American Medical Association which serves both specialists and practitioners, the review confines itself almost entirely to the controversial aspects of breast pathology and in no way gives the practitioner an adequate basis for judging the contents of the book or the merits of its presentation of the major facts concerning the diagnosis and treatment of mammary diseases.

Secondly while the tone of the review is hypercritical, the reviewer does not quote directly the statements of the author criticized but confines himself to generalities which in most instances proceed not from the book but from the opinion of the reviewer. Thus the main part of the review concerns the author's conclusions regarding the relation of chronic cystic mastitis to cancer, discussed in chapter 12. The reviewer states:

The author arrives at the important conclusion that no etiologic relationship exists between chronic cystic mastitis and carcinoma and thus places himself in direct contradiction with an increasing body of opinion (Ewing, McCarthy, Konjetzny, Semb, Cheate, Cutler and others). Warren's recent statistical studies also are opposed to the author's conclusions.

It is noted that this is not a direct quotation by the reviewer and nowhere in the book to the author's knowledge can any such statement be either found nor can it be implied. As a matter of fact the exact opposite is stated repeatedly in chapter 12. Thus on page 265, in discussing the clinical data concerning the relation of these two diseases, the author concludes:

The number of observed cases (in which chronic cystic mastitis and cancer coexist in the same patient) is twice as great as the expected figure and is of etiologic significance although the figure is not high.

In discussing the microscopic data it is stated again on page 269:

However in 6 cases (66 per cent) the histologic appearance suggested origin (of cancer) in an area of mammary dysplasia (fig. 229, 232).

and again on page 272 in discussing experimental data:

To determine if the rat's breast under these conditions is more susceptible to cancer. After one and two years rats with such advanced adenois were given extremely high doses of estrogen for a period of one to two months thus simulating that which may occur at the menopause in women with long-standing adenois (see chapter 34). Under these conditions cancer occurred rapidly in all of the animals (figs. 233-26). Hence long-standing adenois in the human breast may predispose to cancer if this is followed by adequate estrogenic stimulation near the menopause or more rarely at other times in cyclic women.

The entire crux of the matter is then summarized in discussing the follow-up studies on page 276

On this basis, the incidence of mammary cancer in the 793 cases of chronic cystic mastitis is 0.88 per cent instead of the calculated 0.42 per cent. Among the cases of adenosis the cancer incidence is 2 per cent or five times the expected figure. In cystic disease 0.79 per cent or twice the expected figure, and in cases of mastodynia, below the calculated number, or zero per cent.

The histories of the cases of mammary dysplasia in which carcinoma supervened follows

As a matter of fact, throughout the book the relationship of the two diseases is repeatedly emphasized, pages 208, 217, 255, 257, 275, 761 and 800

Not only does the reviewer misrepresent the conclusions of the author arrived at in chapter 12 but he also distorts the facts

The reviewer states that large numbers of cases, as high as 70 per cent in some categories (note the generality, some categories) have no microscopic proof. But, in truth, in the tabulated follow-up studies of cystic disease and adenosis (which are the only forms of mammary dysplasia in which any one has assumed or claimed a relationship to cancer) 80 per cent of the 579 cases have microscopic verification. In cystic disease 50 of 387 diseases are microscopically verified, and in adenosis 113 of 192 cases

The reviewer accepts unquestionably the studies made by Warren along similar lines, while attacking the studies of the author, claiming the two studies to be in opposition. He overlooks the fact that the two studies are in agreement. He is apparently unaware that the much maligned chapter 12 was submitted to Dr. Warren in proof form before publication and some of his suggestions were incorporated in it, to wit, as stated on page 280, in the paragraph beginning with

The incidence of mammary cancer in patients with chronic cystic mastitis is too low to warrant mastectomy. This is the opinion of Warren and also of the author

and ending with

In those cases where a definite nodule develops subsequent to the excision of a former nodule in adenosis, a simple mastectomy may be advisable

A further example of the way in which the reviewer has distorted the facts is illustrated in the statement

Studies of the breast by means of whole serial sections are opposed to the conclusions of Geschickter who did not examine his specimens by Cheate's method

This assumption is entirely false and unwarranted, since many of the author's cases were thus studied, and by merely thumbing through the book and looking at the pictures this fact can be verified, for instance, figures 163, 179, 202, 242, 275, 285, 288, 289, 367, 368, 402 and 410

A similar distortion of facts is found in the statement in regard to the author's classification of mammary carcinoma

Meaningless names are given to microscopic appearances of fragments of tissue from the breast

This statement neglects the fact that the author devotes an entire chapter to each of the forms of mammary cancer presented in his classification, describing and basing the classification not on microscopic fragments but on a careful analysis of both clinical and pathologic features of the disease as well as its response and behavior under treatment, as determined by follow-ups. Not a single new classification of cancer has been introduced. The only novel departure is the introduction of the word "neomammary" for a group of rare cancers previously classified as cancer cysts and sweat gland cancers

CHARLES GESCHICKTER,
Lieutenant Commander, USNR

SUBJECTIVE REACTION TO PROSTIGMINE IN TREATMENT OF POLIOMYELITIS

To the Editor—The use of prostigmine in the treatment of poliomyelitis would seem to merit encouragement. Through circumstances explained below it was necessary to deal with the patient's subjective reaction to the drug, as well as with the objective findings

A white girl aged 19 years, admitted to the Maine General Hospital in Portland, Maine, on Oct. 6, 1942 with the diagnosis of poliomyelitis, received the Kenny treatment there. On November 14, when she left the hospital, she was able to walk with difficulty on crutches through a small room. She continued taking exercises as advised in the hospital, though she improved slowly. In April 1943 she was started on prostigmine bromide and thiamine hydrochloride. The doses used were 15 mg. of prostigmine bromide and 5 mg. of thiamine hydrochloride given orally three times a day. Since she lived 15 miles away and it was impossible to observe the course of the convalescence closely, she was urged to keep a diary. The patient's diary reads as follows:

"The week before I started taking the pills I tired very easily, both while sitting and while standing and walking. I started taking the pills on a Monday and the following Wednesday I began to feel better generally, that is, I could walk and sit longer without tiring. Thursday I noticed an improvement in the muscle in the back of my leg while doing exercises (lying on stomach and lifting whole leg straight up). Friday I noticed an improvement in the muscle which takes my leg out to the side (lying on back, pushing leg out to right side). The second week of taking the pills I didn't seem to notice any definite improvement in any one muscle, it just seemed to be all over. I can walk much farther and longer than I could, but I still limp almost as much."

Before taking prostigmine she could walk through three rooms once a day. She could not abduct or flex the right thigh. After taking it for four days she could perform both exercises, abducting and flexing the right thigh. After taking it for a week she could walk through the same three rooms seven times a day. She also could sit up without aching. She retained all the improvement derived from the treatment.

It is felt that the earlier prostigmine is used in the course of any case of poliomyelitis the better the results will be. Victims of the disease should not be deprived of a trial of this drug, regardless of the time since the onset of the disease.

GEORGE GEYERHAHN, M.D., South Portland 7, Maine

TOXIC ERUPTIONS DUE TO AMPHETAMINE SULFATE

To the Editor—In the treatment of over 2,000 cases of obesity, in which between one-third and one-half million 10 mg. tablets of amphetamine sulfate were used, there were only 2 cases of skin eruptions similar to those described by Kruvar, Henschel and Ravin in the August 14 issue of *THE JOURNAL*.

A careful history and time-taking checking on both patients revealed that each had had a similar eruption prior to taking amphetamine sulfate. Both admitted that when they ate too much tomatoes, real, pineapple, strawberries and other acid foods these eruptions were sure to appear.

The patients were then instructed to omit these foods, take some milk of magnesia for a while, and to apply phenolated calamine lotion locally. These eruptions soon cleared, although amphetamine was not discontinued but even increased in dose for the following week.

MEDICOLEGAL ABSTRACTS

Medical Practice Acts Revocation of License for Conviction of Crime Involving Moral Turpitude while Defendant Confined in Penitentiary—Henry J Schireson who was licensed to practice medicine and surgery in New Jersey was convicted, after a plea of nolo contendere in a federal court of (1) unlawfully concealing assets from a trustee in bankruptcy (2) making a false oath in bankruptcy proceedings and (3) perjury and was sentenced to and confined in a federal penitentiary in Pennsylvania. Subsequently and while he was confined in the penitentiary a complaint was filed with the state board of medical examiners of New Jersey charging that he had been convicted of crimes involving moral turpitude which is one of the grounds enumerated in the New Jersey medical practice act for the suspension or revocation of a license to practice medicine and surgery. The board accordingly notified Schireson in writing that it would, in Trenton N J on Feb 18 1942 hold a hearing to consider whether or not it should suspend or revoke his license. On his request made through his attorney, the hearing was postponed to March 18 and again to April 15 but the board would grant no further postponements and proceeded on the date last mentioned without Schireson's presence with the hearing ultimately revoking his license to practice. The federal convict brought certiorari in the supreme court of New Jersey to review the order of revocation.

It was contended that the revocation of Schireson's license was illegal because (1) the New Jersey medical practice act was unconstitutional in that it served to deprive him of liberty and property without due process of law and that assuming the validity of the medical practice act, the course followed by the state board of medical examiners violated the constitutional safeguard referred to, (2) the order of revocation was not based on legal evidence and (3) the refusal of the board to grant further adjournment or continuance was capricious. The essence of Schireson's case, said the appellate court is that the possession of his license was a property right and that the refusal of the board of medical examiners to continue the hearing of the charge against him until he was released from the penitentiary deprived him of the opportunity to defend and therefore was not due process and ancillary to this is the contention that the record of criminal proceedings did not disclose an adjudication or a plea that he was guilty of the offenses for which he was indicted and that therefore he could not be subjected to the revocation of his license except on proof

of guilt produced before the state board on original charges of unlawful concealment of assets, false swearing, perjury, or whatever offense might be laid against him. It is not denied, continued the court, that the crimes for which he was sentenced by the federal court involved moral turpitude. The state board was authorized to proceed on proof, not that Schireson was guilty of the named crimes, but that he had been convicted of them, and it is not denied that the court record of the indictment, the pleas, the conviction and sentence, in fact the whole pertinent record, was put in evidence before the board.

Schireson, continued the court, had a legal claim to his license. We need not, however, determine whether his authority to practice in New Jersey was a privilege or a right or, if a right, whether just that or, more specifically, a property right. By whatever name, it was subject to the paramount right of government to protect the general health of the members of society—the police power. It was for the legislature to determine, within reasonable limits, what the tests of moral character in a physician should be. The circumstance that Schireson had already been licensed gave him no immunity against such legislation. *Lawrence v. Bruy*, 239 Mass. 424, 2 N. E. 174. He had no vested right to practice after he had been found to have qualities inconsistent with good moral character. Character, as well as knowledge and skill, should be resident in one who would practice the art of healing and thus have intimate responsibility for the health and lives of human beings, and it is a reasonable exercise of legislative power to determine that a person who has committed a crime of moral turpitude is not such a one as should be permitted to practice medicine or surgery. It may be said with respect to the practice of medicine, as Justice Cardozo said with respect to the practice of law in *McCormick*, 221 N. Y. 81, 116 N. E. 782, 783, in part as follows:

Membership in the bar is a privilege burdened with conditions. A fair private and professional character is one of them. Compliance with that condition is essential at the moment of admission, but is equally essential afterwards.

The legislature of a state may enact that one who has been convicted of crime shall no longer practice medicine. *Hawker v. State*, 170 U. S. 189, 18 S. Ct. 573.

Schireson attempted to draw a technical distinction between a conviction and that congeries of events which began with his plea of *nolo contendere* and terminated in his being lawfully sentenced and in his submitting to the imprisonment which the sentence imposed. But, said the court, there can be no well grounded dissent from the proposition that so far as the state was concerned there was a conviction. True, there was no jury verdict of guilt and there was not a technical plea of "guilty," and if Schireson had been sued in a civil action he would have had the benefit in his defense of such rules as hinge on that distinction. But the proceeding before the board of medical examiners was not a civil action. In our opinion the proceedings in the federal court constituted a conviction within the meaning of the New Jersey medical practice act.

Schireson argued, however, that he was entitled, notwithstanding his conviction, to have his original guilt proved before the board of medical examiners by witnesses and exhibits as though there had been no conviction and as though the charge before the board was that he was guilty of the alleged offenses and not that he had been convicted of them. Clearly, said the court, that was not the requirement or the intent of the medical practice act and was not made necessary by any provision of the federal or of the New Jersey state constitution. It would be a strange eventuality for Schireson, after his guilt had been so plainly established with respect to the commission of the criminal offenses with respect to the practice of his profession, to be found not to have committed those crimes. This proceeding is merely one to give effect to a provision of the medical practice act relating to the practice of medicine and surgery which says that the board may revoke on the conviction of a crime of the designated class. As was said in *Hawker v. State*, 170 U. S. 189, 18 S. Ct. 577:

The thought which runs through these [viz., the cited] cases and others of similar import which might be cited is that such legislation is not to be regarded as a mere imposition of additional penalty, but as prescribing the qualifications for the duties to be discharged and the position to be filled, and naming what is deemed to be and what is in fact appropriate evidence of such qualifications.

The only issue before the board of medical examiners was whether Schireson had been convicted of a crime involving moral turpitude, he had been so convicted and that fact was proved from the court records—competent evidence for that purpose. The question of guilt or innocence, as such, was not in issue, Schireson had had his day in court on that.

Schireson next contended that the New Jersey medical practice act was unconstitutional in that it did not require that an accused physician be notified of the proceedings or be given an opportunity to be heard and that the board of medical examiners acted unconstitutionally because its proceedings found him in such predicament, because of his imprisonment, that he could not attend. Be it observed, however, answered the supreme court, that while the medical practice act does not, where the cause for suspension or revocation is the conviction of a crime, require the "hearing"—really a trial—which it directs shall be accorded where the cause is the commission of an offense for which there has been no prior conviction, nevertheless it does provide that notice shall be given of the purpose of the board to sit in disciplinary session, and as a matter of fact notice was given of the session, and given in such fashion that Schireson had full advance knowledge thereof and indeed appeared by counsel to the extent of obtaining two adjournments. It is not a condition of due process that the defendant shall be, or shall be able to be, physically present at the hearing. The board's refusal to grant further adjournment was not capricious. The order of revocation contained an ample statement of the evidence on which the revocation was based.

The court concluded that neither the medical practice act nor the procedure followed in revoking Schireson's license was unconstitutional in the respects complained of, that the finding of the board of medical examiners was grounded in legal evidence and that its refusal to grant further adjournment was neither capricious nor otherwise illegal. The order revoking Schireson's license to practice was therefore affirmed.—*Schireson v. State Board of Medical Examiners of New Jersey*, 28 A (2d) 879 (N. J., 1942).

- Wisconsin State Medical Society of Milwaukee, Sept. 13-15. Mr. Carl H. Crownhart, 110 East Main St., Madison. Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1911 to date. Reprints for issues of earlier date cannot be filled. Reprints should be accompanied by stamps to cover postage (6 cents if one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied in purchase order. Reprints as a rule are the property of authors and can be ordered for permanent use at only 1 cent each.

Genetic Factors in Tuberculosis Studies on Twins—Kallmann and Reisner investigated the possible significance of genetic factors in the development of tuberculosis by means of the twin family method. This method combines the technique of the original twin method that is the comparison of unselected groups of one egg and two egg twin pairs with the principles of a family study including the other sibship groups as well as the marriage partners of the twins. The main objective of this procedure was to obtain for comparison a sufficient number of genetically dissimilar relationship groups reared under comparable environmental conditions. The study was organized with the cooperation of the tuberculosis hospitals and clinics in the state and city of New York, which

reported a total number of 637 twin cases within a period of five years. The material used for analysis of the statistical data on manifest reinfection tuberculosis consists of 308 complete twin families with 616 twin partners, 930 full siblings, 74 half siblings, 648 parents and 226 marriage partners of twin patients. The random sampling of these 308 twin pairs is indicated by the proportion of 78 monozygotic to 230 dizygotic pairs representing a ratio of about 1:3. Comparison of the corrected morbidity rates reveals that the chance of developing tuberculosis increases in proportion to the degree of blood relationship to a tuberculous index case. The difference in morbidity between dizygotic and monozygotic twin partners amounts to a ratio of 1:35, their corrected concordance rates being respectively 25.6 and 87.3 per cent. The difference between the dizygotic and monozygotic co-twins increases to a ratio of 1:16 if the similarities in extent, course and eventual outcome of the disease are taken as additional criteria of comparison. The differences in tuberculosis morbidity among the various sibship groups of the twin index cases cannot be adequately explained on the basis of a simple correlation between closeness of blood relationship and increasing similarity in environment with correspondingly intensified opportunity for infection. The analysis of the morbidity distribution in the sibship groups indicates that resistance to tuberculosis is modified by a heredoconstitutional mechanism which seems to be multifactorial in its genetic nature.

Demonstration of Tubercle Bacilli in Minimal Pulmonary Tuberculosis—Decker and his associates insist that demonstration of tubercle bacilli is required to clinch the clinical diagnosis in minimal pulmonary tuberculosis. They present the results obtained with the intensive use of the more thorough laboratory methods. Repeated examinations of sputum and of fasting gastric contents by culture and guinea pig inoculation resulted in the demonstration of tubercle bacilli in 67 out of 97 patients with clinically active minimal pulmonary tuberculosis over a period of five years. In a previous five year period when the more thorough laboratory methods were not in routine use tubercle bacilli were demonstrated in only 24 of 172 cases. Gastric lavage studies gave positive results in 41 of 56 no sputum cases. Sputum smears were positive in but 16 of 269 cases. A high percentage of patients with clinically active minimal tuberculosis discharge tubercle bacilli. It is difficult to determine when patients with minimal disease are entirely free from bacilli. It is just as difficult to evaluate the significance of the discharge of a few bacilli on rare occasions.

Streptococcal Bacteria Cured with Sulfadiazine—A man aged 65 for several months had been troubled with general fatigue, muscle aches and shortness of breath. He had suffered an attack of sharp, severe pain in the chest below the nipple on the left side. The pain radiated to both axillae and caused difficulty in breathing. He had one moderately severe chill

Chills sensations occurred at intervals. A superficial ulcer of the left thigh was noted on admission to the hospital. Small, pinkish red, maculopapular lesions were scattered over the entire body. There was a generalized reddening of the skin over parts of the trunk and extremities similar to a scarlet fever rash. Blood examination disclosed aplastic anemia, and the blood culture was positive for hemolytic streptococci. Lancefield group C. There was a rapid improvement following sulfadiazine therapy. The blood culture was negative for hemolytic streptococci on the third day of hospitalization. The cause of the aplastic anemia was not apparent but probably was not the streptococcal infection. The patient had had symptoms of the underlying disease for three months before chills and fever appeared, suggesting that the bacteremia was an intercurrent episode made possible by a lowering of the natural defense mechanism. The response to sulfadiazine was remarkable considering the age and the poor general state of the patient. The source of infection was probably the superficial ulcer on the left thigh. Group C organisms are occasionally isolated from human skin. The rash was of interest in view of the fact that scarlet fever has been known to have been caused by group C organisms. Immunologic studies in the reported case by Kirby and Rantz suggest that fibrinolysins and streptolysins O of groups A and C are similar if not identical. Since 95 per cent of infections with hemolytic streptococci in human beings are caused by organisms belonging to group A (Lancefield), the opinion has become generally accepted that members of the other groups are relatively avirulent. This point of view may have to be modified. Severe infections have been caused by members of groups other than A, chiefly by groups C and G, suggesting that the frequency of infections with organisms of the various groups may be partly a matter of distribution of the organisms rather than of virulence. Organisms belonging to groups A, C and G have certain characteristics in common which are different from those of members of the other groups. These three groups are the ones most commonly isolated in the order named in infections in human beings, and this may be in part due to their unique properties.

Spontaneous Interstitial Emphysema of Lung—Hamman was first to report this condition in healthy persons without antecedent trauma or disease. The condition is largely dependent on the collection of air in the mediastinum. The onset is abrupt. The first symptom is a severe pain in the side of the chest or substernally. It may radiate to the neck or down the left arm closely mimicking the pain of coronary occlusion. The pathognomonic sign described by Hamman is a peculiar crackling, crunching sound heard over the sternum which is synchronous with the heart beat. There may or may not be signs of pneumothorax. A small amount of subcutaneous emphysema in the neck or thorax is sometimes present. Roentgenograms may or may not demonstrate the mediastinal air. The process has been benign in all instances, complete recovery occurring in several days. Adcock describes a case of spontaneous interstitial emphysema of the lung with extension of air into the retroperitoneal and subcutaneous tissues. The absence of pain in this case may have been due to the ease of escape of the air from the mediastinum which prevented the development of high mediastinal pressures. A small area of transient atelectasis was apparently responsible for the development of the interstitial emphysema of the lung. It was possible to locate clinically the site of escape of air from the alveoli into the perivascular and interstitial tissue of the lung. The auscultatory signs produced by air within the mediastinum differ in type and mode of production from the so-called pericardial knock sounds occasionally heard in left sided pneumothorax, whether spontaneous or induced.

Blue Scleras, Brittle Bones and Deafness—Farber and Margulis observed a family of 52 members, 12 of whom presented the syndrome of blue scleras. Seven of these have brittle bones, 4 are deaf and 1 has only blue scleras. Eight are males and 4 females. The condition is transmitted and occurs equally in the two sexes. The physical attributes of small stature, hypermobility of the joints, relaxation of the ligaments and abnormal shape of the head were found in the involved mem-

bers. Three members of the group have been studied in detail. Roentgenograms of the skeleton revealed slender bones, generalized osteoporosis and deformities resulting from multiple fractures.

Adrenal Cortex in Systemic Disease—Sarason attempted to establish correlations between changes in the morphologic aspects of the adrenal cortex and various systemic diseases. Adrenal glands were obtained from one hundred and ten routine autopsies performed at the New Haven Hospital one to six hours after death. No glands from persons with Addison's disease or primary neoplasm of the adrenal gland are contained in the series. Cortical enlargement associated with depletion of lipid or reversal of lipid pattern was found associated with inflammatory diseases, cachexia, pemphigus and protracted emesis. Cortical enlargement with an increased amount of lipid was encountered in hypertension, the change was more striking when the hypertension was associated with primary vascular disease. The explanation of these changes is not at hand. No significant alterations were present in the series of cases of atherosclerosis. Extreme enlargement was found in 4 cases of erythroblastosis fetalis. This study emphasizes that enlargement of the adrenal cortex and depletion of lipid are reflections of the metabolic disturbances associated with certain systemic diseases and not the direct effect of the latter.

Preserved Erythrocytes After Transfusion—The purpose of the studies reported by Denstedt and his collaborators was to determine the merits of two blood preservative mixtures, the one an unbuffered citrate-dextrose solution, the other buffered with phosphate at pH 7.4. Both mixtures were isotonic with normal plasma. Blood can be stored in these solutions up to six weeks or two months at 4°C with less than 1 per cent hemolysis. The buffered solution gives slightly better cell preservation during storage and favors less dense packing of cells on sedimentation. The survival of erythrocytes after transfusion was followed in 32 mental subjects by the MN method of Wiener. Specimens stored up to two months were used without any reaction. With regard to cell survival the buffered mixture did not exhibit special merit. The study indicates that cells stored up to eighteen days by either method survive as well as fresh cells after transfusion. Even with 25 or 30 day old blood cell survival after transfusion is sufficiently high during the first three weeks to warrant the use of such specimens in the treatment of severe blood loss when fresher blood is not available. There is evidence that with

of the transused cells may be stored instead of being destroyed and that they are released into the circulation again between the fifteenth and twenty-fifth days. A second and less decided rise in donor cell count often is observed about the sixtieth day.

Whipple's Disease (Lipophagia Granulomatosis) — Whipple in 1915 described a disease characterized anatomically by deposits of fat and fatty acids in the intestinal and mesenteric lymphatic tissues, which were greatly enlarged, the normal structure being replaced by dilated fat-filled lymphatic spaces and granulomatous tissue. The same or a similar condition has been described by others as intestinal lipodystrophy, lymphadenectasis, lymphadenocoele mesenteric chyladenectasis and lipophagia granulomatosis. Apperly and Copley report a case of lipophagia granulomatosis and compare it with 11 other

cases. The disease appears in men aged 40 to 60 with indigestion gaseous distention and often a history of polyarthritis. Later there is diarrhea or steatorrhea, often with blood, severe wasting and weight loss, moderate anemia and edema, low blood pressure achlorhydria and often some skin pigmentation or icterus. Necropsy reveals filling of the intestinal mucosa with large fat filled foamy macrophages, greatly enlarged mesenteric lymph nodes composed of granulomatous tissue containing dilated lymphatics filled with lipid and surrounded by macrophages and giant cells, and often chylous ascites, moderate fibrous pleuritis pericarditis and peritonitis.

Plumbism Resulting from Cutting Painted Steel — Tabershaw and his associates point out that the discovery of several cases of lead poisoning in a group of oxycetylene burners engaged in cutting painted steel has brought attention once more to a hazard which was extremely common during and after the first world war. The report concerns 14 men engaged in salvaging an old elevated railway structure. All the workers except two were supplied with mechanical filter respirators approved by the Bureau of Mines for use against toxic metal fumes. The filters were changed daily. Two men were supplied with canister type respirators containing a felt filter and a charcoal soda-lime mixture for the removal of acid gases and vapors. In the course of the salvage operation practically all the men were ill at one time or another with some slight or major symptoms of lead poisoning. The authors present two typical histories. The evidence is overwhelming that the cutting of structural steel covered with lead bearing paint is a potential source of plumbism and that neither the use of respirators nor natural ventilation provides complete protection. Nevertheless the wearing of approved respirators should be insisted on during the entire work period. Medical examinations should be done periodically including blood and urine studies. Workers who develop signs or symptoms of plumbism should be transferred to jobs which do not present the same hazard. At present there is a great deal of oxycetylene cutting being done in the repair of damaged ships. Burners cut painted steel to suitable size and shape. There can be no doubt that the workers are exposed to a serious lead hazard.

Isoimmunization with Rh Factor—Dameshek and Levine report that a patient with subacute acquired hemolytic anemia developed severe and almost fatal hemolytic reactions when given successive blood transfusions. Subsequent testing revealed that the patient (group O Rh—) had developed isoimmunization to the Rh factor with the presence in the blood of both a warm anti Rh agglutinin and a cold agglutinin. Transfusions with Rh— blood were without reaction. Splenectomy and biopsy of the liver showed intense myeloid metaplasia of both organs. Death resulted from acute toxic necrosis of the liver. Necropsy revealed widespread myeloid metaplasia in the presence of severe hemolysis. Repeated transfusions in acute hemolytic anemia may be followed by isoimmunization and the development of irreversible hemolysis. As the result splenectomy, which might originally have been curative, may prove ineffective.

Immune Rabbit Serum in Rocky Mountain Spotted Fever—Topping reports his experience with immune rabbit serum in the treatment of laboratory animals infected with the virus of Rocky Mountain spotted fever. The serums used were from two sources and differed only in the antigen used for the active immunization of the rabbits. The methods of concentration and purification were identical. The T serum was prepared with tick antigen and the L serum by the use of infected yolk sac material. The experiments indicate that it is possible to produce an immune serum in rabbits by the use of live virus either from infected ticks or from infected yolk sacs. Administration of this serum to infected guinea pigs and monkeys demonstrated its therapeutic value when given early. With small doses the therapeutic effect varied inversely with elapsed time from the inoculation of the infecting dose to the administration of the serum. If given within twenty-four hours after infection it would completely suppress the disease. If a small dose was given from forty-eight to seventy-two hours after the infection it would modify the disease in such a manner as to prevent death as well as the scrotal reaction of spotted fever in guinea-pigs. This small dose was of no value after seventy-two hours, but if the dose was increased benefit could be demonstrated as late as one hundred and twenty hours after infection (the second day of fever). The results of the human trial are not conclusive because of the small number of cases. The fatality rate in cases treated before the third day of rash was considerably below that expected from past experience with patients receiving no serum. There were only two deaths in the 52 cases treated. Of the 52 patients treated only 2 died, both of whom were men aged 66 and 72 respectively, or a fatality rate of 3.8 per cent as compared to the expected rate of approximately 18.8 per cent. Anti-Rocky Mountain spotted fever serum should be considered as offering hope in the treatment of this disease.

Infective Hepatitis—Ford reviews 300 cases of infective hepatitis which occurred in Wembley, an outer London borough. These 300 cases form part of a larger outbreak extending over surrounding districts. The only death among them was that of a boy aged 16 who was hospitalized in coma and died of hepatic failure three days later. Water, milk or foods could not be suspected as sources of infection nor could the infection have been spread by rodents. With few exceptions the patients all reported known close contact with other persons who either were suffering from the disease or had just recovered. Most patients showed well defined prodromal symptoms such as mental depression, irritability or drowsiness, with loss of appetite and constipation often accompanied by headache with pain in the right epigastrium, sometimes diagnosed as acute appendicitis. Many patients complained of shivering attacks and a few of muscular tenderness or photophobia. After three or four days nausea and vomiting appeared and there was a rise of temperature. Bile in the urine appeared on the fifth or sixth day of the illness and was followed in twenty-four to forty-eight hours by jaundice. The jaundice commenced always in the ocular conjunctivas and often spread to the face, neck, abdomen and the whole body. With the onset of jaundice there was in most cases a remarkable improvement in the patient's general condition. The liver was found to be moderately enlarged but the spleen could not be felt. Many patients lost several pounds. The jaundice usually cleared within one to three weeks. Confinement to bed for a few days with restriction of fats and increase of carbohydrates were effective measures. Calomel was a useful purgative. Both home and school contact could be blamed for the spread of infection. As the infective agent has not been isolated and as it appears that the incubation period is long the only suggestion put forward for the control of the infection is that during an epidemic, children who vomit in school should be excluded for seven days.

Transmission of Jaundice Following Yellow Fever Immunization by Intranasal Instillation—Findlay and Martin point out that in 1937 attention was called to the occurrence of jaundice following yellow fever immunization. Evidence was brought forward to show that this jaundice had nothing to do with the yellow fever virus as such but was probably due to some agent in the human serum used in the preparation of the vaccine. It was considered possible that this icterogenic agent had multiplied together with the virus of yellow fever in a serum-Tyrodé culture medium containing minced chick embryo. When the technique of preparing the vaccine was altered by employing only serum taken from donors who had remained in perfect health for a month or more after the serum had been withdrawn and by inactivating the serum for at least thirty minutes at 56°C, no further cases of post-inoculation jaundice occurred in the many thousands of persons immunized in England and Africa from November 1937 onward. Similar precautions taken in Brazil also resulted in the elimination of jaundice as a sequel to yellow fever immunization. Recently jaundice has been reported among American army personnel inoculated with yellow fever vaccine and within the last few months between 250 and 300 cases of jaundice have again been seen following yellow fever immunization in Britain. All attempts to transmit the disease to the usual laboratory animals having failed it was determined to investigate the possibility of transmission to human beings. Four men volunteered. They had never suffered from jaundice. All were immune to yellow

fever, having been immunized eight months previously from a batch of vaccine that had not produced jaundice in any person. Washings were obtained from the nasopharynx of patients with icteric or preicteric symptoms following yellow fever inoculation. For instillation into the nares the volunteers were placed flat on a couch with the head hanging over one end. The nasal washings were then slowly dropped into the nostrils of the volunteers, who were told to sniff. Of the 4 volunteers 1 has shown no evidence of illness. There is doubt whether the patient with whose nasal washings he was inoculated ever suffered from postinoculation jaundice. Of the 3 others, 1 had subclinical icterus associated with mild symptoms. Two however suffered from jaundice. The results so far obtained with jaundice following yellow fever immunization show that in the nasal washings from patients in the preicteric and possibly icteric stage there exists an agent which is capable of inducing jaundice in human volunteers with symptoms similar to those of infective hepatitis after an incubation period varying from thirty to fifty days.

Treatment of Immersion Foot by Dry Cooling—Ungley describes the methods employed by Webster and his colleagues in treating cases of immersion foot in the hyperemic stage by dry cooling. (a) Dry ice bags were placed round each foot and changed every four hours or oftener if necessary to reduce skin temperature by about 6 degrees C. (b) the feet were fanned with air cooled by cold water sprayed from a nebulizer. (c) the feet were exposed to room temperature in a cool ward. Pains were relieved and the patients were comfortable within four hours. Edema usually subsided rapidly and contents of blebs were absorbed. In several cases impending gangrene was arrested. Ungley had an opportunity to try methods of dry cooling in immersion foot in the hyperemic stage. Two men were rescued after exposure for thirty-four hours on a raft in the North Sea, reaching the hospital a few hours later. Their feet were cold blue and moderately swollen. During the night the feet became hot (32 to 34.5°C or 89.6 to 94.1°F) and more swollen. Ungley's experience in these cases confirms Webster's observation that cooling the hot limbs relieves pain and tingling. Exposure of the feet to a cool room temperature (15 to 18°C, or 59 to 64.4°F) with a fan playing on the soles proved a simple and satisfactory method. It was not found necessary to spray cold water through the fan or to use icebags. The speed and distance of the fan were adjusted to maintain skin temperatures of from 23 to 26°C (73.4 to 78.8°F), cooling to less than 21°C (69.8°F) gave rise to discomfort. The author thinks that for severe cases requiring long, uninterrupted cooling and not intolerant to restriction of leg movements, Greene's therapeutic refrigerator might prove useful.

*Tonsil Adenoid Operation in Relation to Health of Group of School girls. J. H. P. Paton—p. 119

Galactose Tolerance Tests in Thyrotoxicosis. C. G. Barnes and E. J. King—p. 129

Familial Hemolytic Anemia and Splenectomy—Dacie studied erythrocyte fragility to hypotonic saline solution in 24 cases of familial hemolytic anemia. Three main types of quantitative fragility curves could be distinguished—'tailed' curves (12 cases), 'diagonal' curves (6 cases) and 'normal type' curves (5 cases). Splenectomy was performed in 12 cases in 11 of which resistance to hemolysis was increased after operation. In 7 cases with 'tailed' curves increasing in resistance was preceded by a transient postoperative increase in fragility. In 1 case first seen in a hemolytic crisis fragility ultimately became normal in another there was an increase in fragility compared with the preoperative level which persisted for at least three years after splenectomy. Great engorgement with blood was the most notable feature of the 12 examined spleens. Perfusion experiments with excised spleens failed to demonstrate the cause of the congestion. Although it was difficult to free the pulp from blood by perfusion with saline solution the

time of circulation of test objects (fowl erythrocytes) through the spleens appeared normal. The various theories on the pathogenesis of the disease are considered. The available evidence suggests a hemolytic disorder based on the presence of erythrocytes with an increased tendency to hemolysis. Although there is much evidence to support the view that this represents a primary defect in erythropoiesis, experimental and clinical observations on the relationship between hemolytic anemia, splenic congestion and spherocytosis indicate that the possibility of the presence of an abnormal hemolytic agent or metabolite cannot be ignored.

Tonsil Adenoid Operation and Health of School Girls—Paton analyzes the records of 909 girls admitted to a boarding school between 1930 and 1939. The girls are recruited from well to do families and are healthy on admission. The majority enter school at or about puberty. The data are extracted from the history and state of health on examination recorded at entry and the records of illness during the school years. Fifty-seven per cent of the girls had had their tonsils removed and 50 per cent had had their adenoids removed. Inquiry into the incidence of illness among 909 girls revealed that the operation group was no healthier than the control group on arrival at school. The operation group was less healthy than the control group while at school. This is shown by the number of school days lost through illness. The operation group suffered less from tonsillitis. The operation group suffered much more from respiratory infections and lost more days from bronchitis alone than they gained in respect of tonsillitis. When the small groups in whom a single operation was performed (tonsil operation 57 cases, adenoid operation 24 cases) are considered, certain deductions are warranted. Removal of the tonsils is the factor in the combined operation responsible for the reduction in tonsillitis and for the increase in respiratory infections. Adenoidectomy alone reduces the liability to respiratory infections, but in the combined operation group the removal of adenoids failed to counteract the increase in respiratory infections which resulted from the tonsillectomy. Removal of adenoids increases the liability to acute otorrhea. Recurrent attacks of otorrhea are seldom prevented and primary attacks of otorrhea are more frequent after the operation. These figures support the conclusion of Glover and Wilson, arrived at from a survey of more than fourteen thousand records, that a large proportion of the tonsil and adenoid operations now done on children are "unnecessary, entail some risk and give little or no return."

Hashimoto's Disease—Lymphoid goiter is observed in women past 40 years of age. The condition develops slowly, is woody hard on palpation and involves all of the gland. The gland is not adherent to the neighboring tissue. Hypothyroidism is the result. The diagnosis is confirmed by the microscopic examination of tissue removed at the operation. The therapy consists in bilateral subtotal thyroidectomy. Post-operative myxedema is a frequent complication but is readily controlled by administration of thyroid preparations.

Bismuth Compounds in Poliomyelitis—Calabrese used bismuth compounds in the treatment of 58 cases of poliomyelitis with encouraging results. The treatment should be begun early and saturation accomplished as quickly as possible. The author

uses hydrosoluble as well as liposoluble bismuth. The hydrosoluble substance is administered in doses of from 3 to 4 mg per kilogram of body weight. This dose is usually given by intramuscular injection and is repeated after twelve hours, because the hydrosoluble substance is rapidly eliminated (in about twenty-four hours). The liposoluble product is given simultaneously and also by intramuscular injection but in smaller doses (1 to 2 mg per kilogram of body weight) and on alternate days. The liposoluble bismuth exerts a sort of depot action. During the subacute stage only the liposoluble substance is given every other day or every third day. The toxicity is slight, gingivitis was observed in some cases, but it disappeared rapidly after lavage with sodium bicarbonate. Vitamin B can be given in addition to the bismuth, and the symptomatic treatment should be maintained.

Writing Test in Occupational Mercury Poisoning E Holstein—p 170

Sublingual Application of Desoxycorticosterone—Heni reports 3 cases of Addison's disease in which he resorted to the sublingual administration of desoxycorticosterone. He gave the substance in the form of drops as well as in the form of tablets to be dissolved under the tongue. His experience with this method of administration corroborated the report of American authors (Anderson and others) that the sublingual application of desoxycorticosterone acetate can be employed with good results. The absorption through the lingual and oral mucosa is good but is only three fourths that absorbed from intramuscular injection. For this reason the dose must be about one third higher. Gastrointestinal disturbances developed in 1 of the patients, but these were partly due to excessive dosage. The sublingual administration can replace the intramuscular injection as well as the subcutaneous implantation of crystalline substance in the continued treatment of Addison's disease.

Bomskov's Thymus Hormone and Status Thymicolymphaticus—Rechenberger and his associates extracted the thymus hormone according to Bomskov's method from the thymus glands of children who died in status thymicolymphaticus. They tested its effect on the hepatic glycogen of rats and guinea pigs and found it to be indefinite. Thymus hormone was also extracted from calf thymus according either to Bomskov's or to other methods of extraction. The hormone obtained from calves showed no definite action on the hepatic glycogen of test animals. Raw thymus oil obtained from Bomskov himself produced the same results. The glycogen content of the livers of children who died suddenly in status thymicolymphaticus was within normal limits.

Sulfapyridine in Typhus—Menk gave sulfapyridine to patients with typhus in Poland in 1940 chiefly to combat the complicating pneumonias. His observations and those of others seemed to indicate that sulfapyridine was effective for that purpose. The effect on the typhus itself was negative. Animal experiments do not make it probable that sulfapyridine will be effective in human typhus. Tests with numerous sulfonamide compounds revealed only one preparation that had some effect on the Rickettsia mooseri infection of mice.

Book Notices

Operative Oral Surgery By Leo Winter DDS MD F.A.C.D. Professor of Oral Surgery New York University New York. Second edition Fabrikoid Price \$12.50 Pp 1674 with 1211 Illustrations St. Louis C. V. Mosby Company 1943

In the war emergency Dr. Leo Winter felt it imperative to revise the former edition to include important discoveries and developments in the practice of oral surgery. Many dental surgeons will be called on to provide first treatment to a large number of war casualties which differ but slightly from traumatic wounds occurring in civil life in these days of too frequent automobile accidents. At the battle front the armamentarium for proper treatment is not always at hand therefore Dr. Winter has presented the simplest and most expedient methods of treatment to bring the desired results.

Amplifications cover chemotherapy, shocks, burns, war wounds, dislocation and subluxation of the temporomandibular articulation, pin fixation or skeletal fixation for treatment of fractures, general anesthesia and oral manifestations of blood dyscrasias. A foreword gives a warning to the student of oral surgery of the necessity of a complete knowledge of anatomy and physiology. He should be able to visualize the parts as clearly as if the coverings of the jaws were transparent. The skillful oral surgeon has accurate knowledge of the jaws, sinuses and structures in the floor of the mouth and neck and their mutual relations.

Various methods of local anesthesia and their technic are described in detail, with colored illustrations to show nerves, arteries and veins to locate the point of puncture. When a general anesthetic is required inhalation anesthesia is today the principal medium for control of pain. Minimizing the dangers to the patient is of serious importance. Respiratory obstruction must be carefully watched during oral surgery as it may result in the upper air passages, from anatomic distortions, operators' instruments, packs or hands, laryngospasm and from anesthetic appliances. Lower respiratory obstruction may be caused by aspiration of blood or secretions. A special anesthetist is required by the oral surgeon so that he may concentrate on surgery without the responsibility of watching the effect of the anesthetic on the patient. Special consideration should be given to the type of anesthetic to fit the idiosyncrasies of the patient. In emergencies the anesthesia problem has to be met with the most expedient method that the conditions and supplies permit.

In exodontia special consideration is given to roots in antrums and impacted teeth. In pericoronitis x-ray films are useless in diagnosis but valuable in deciding the technic to be employed when the removal of the tooth is indicated. Pain and its manifestations in various neuralgias are described and differentiated. The pain in tic douloureux is the most severe and surgery the only cure. It definitely is not of dental origin. Swellings of the face and neck present a diagnostic problem, as they may be of dental origin or a definite manifestation of diseases which must be correctly determined and properly treated. Blood dyscrasias are often first manifested in the mouth and recognized by the oral surgeon. A brief outline gives the major features of the various hematologic and related conditions which may be associated with oral manifestations.

Differentiation between adamantinomas and cysts is of utmost importance, as it is essential to resort to proper treatment at the outset. Clinical diagnosis should be supplemented by x-ray examination and a biopsy, which will be the determining factor. Periodic x-ray examination of the teeth and systematic clinical examination of the mouth are safeguards against any abnormalities developing to a stage requiring mutilating surgery.

Dental prosthesis sometimes requires oral surgery in preparation for correction of the bone structure and tissue formation in the mouth to obtain perfect fitting dentures. When treatment and occlusal adjustment fail to clear up pyorrhea pockets the dentist must resort to surgery using either the so-called flap operation or gingivectomy. Fractures are usually caused by some form of trauma but there are also systemic causes which must be considered. The history followed by careful

examination will reveal symptoms of diagnostic significance. Then the best method for immobilization of the part may be determined. Loss of a segment of bone from osteomyelitis removal of a malignant growth or a certain type of injury may require a bone graft, which must be esthetically and functionally correct to reconstruct the lost part.

In the chapter on chemotherapy the clinical action of sulfanilamide on various types of organisms is presented with its relative merits. In oral surgery sulfathiazole has surpassed sulfanilamide for treatment of infectious processes because of the reduced toxicity of sulfathiazole. In the treatment of war wounds in the soft tissues of the face observations of surgeons are that sulfanilamide is superior to sulfathiazole in bacteriostatic activity.

The same problems present themselves in the case of wounds whether they occur in civil or in military life. The factors of respiration shock, hemorrhage, fracture, infection, foreign bodies and transportation of the individual are always prevalent. Respiration should be watched to make sure there is no obstruction; treatment for shock should be given before its onset rather than after and the control of bleeding is vital for the maintenance of life. After treatment of the wound and removal of foreign bodies where it is advisable, the maintenance of space is important for future surgical consideration. The future success of plastic surgery will depend upon the wisdom and ingenuity of the oral surgeon in the immediate treatment. When the features have completely collapsed as a result of loss of bony substance, it becomes an impossibility for the plastic surgeon to recreate the individual part. Orthodontic and prosthetic appliances should be employed to prevent the collapse of bony fragments.

Surgical treatment of prognathous mandibles is an interesting study. Shortening of the mandible may be accomplished in a relatively short time and harmony in relative size of the mandible to the maxilla may be produced with satisfactory functional and esthetic results. Conversely, in underdevelopment of the mandible it may be extended to a proper relationship between the two jaws. Every operative procedure is so carefully illustrated step by step that this book might be classed as visual education.

Doctor in the Making: The Art of Being a Medical Student By Arthur W. Ham M.B. Associate Professor of Anatomy in Charge of Histology Faculty of Medicine University of Toronto Toronto Ontario and M.D. Salter M.A. Ph.D. Cloth Price \$2 Pp 179 with illustrations by Jean McConnell Philadelphia Montreal & London J. B. Lippincott Company 1943

Here is an engagingly written and amusingly illustrated little book which fulfils the promise of the preface that 'It deals with the motives and mental equipment that are necessary if one is to be a successful medical student and—with the common enemies of success. It contains many valuable hints and guides for the student in any field but especially for the high school and college student who is looking toward medicine as a career, as well as for medical students for whom it is designed primarily. For those members of the faculty also who lack adequate insight into the motivations and difficulties of the present day medical student in adjusting himself to the increased scope and greatly expanded content of the medical course the book is especially recommended.

The authors have written from their rich experience at the University of Toronto as faculty advisers of medical students. The fact that ability and academic preparation do not guarantee success unless habits of study attitudes general personality characteristics and other factors properly condition the student for his life of study is the ripe fruit of their experience (as it has been of others) and the well illustrated theme of this book.

The book is more than a helpful guide to the poorly adjusted or bewildered student; it is also an excellent medicopsychologic analysis of personality and character in terms of the essential elements which determine the conditions for success in life. The chapter for example on the child self as a handicap to success in adult life is a condensed course in psychobiology which if adequately digested will lead to greater self understanding and insight. That this is essential for any one who hopes to be an understanding and respected physician

—and incidentally a successful one—is the secondary, if unexpressed theme of the book. This is an effort on the part of the authors to cure the student of incipient and actual maladjustments through the process of education as a first step in practicing the aphorism 'Doctor, cure thyself' if he is to realize the full responsibilities and greatness of a physician. The chapter on "Understanding and Applying the Scientific Method" is a further analysis of scientific thinking as contrasted with delusional thinking. The student who understands this chapter is well equipped to guard himself against the pitfalls of rationalization and deduction so often the cause of faulty reasoning and diagnosis.

Finally under the title of "Do's and Don'ts for the Student" it is pointed out that the "medical student automatically assumes some of the responsibilities of the profession." This chapter is a fitting conclusion for it emphasizes the human values in the culture of medicine, a culture which studies man in all of his multifold activities and at all levels of his existence. The authors think that "in general the average medical student or physician does not appreciate the cultural value of his knowledge and the great need for him to use this knowledge as a leaven for community opinion." The old fashioned country doctor "was not afraid to let the weight of his opinion be felt in community life, and he was not infrequently the greatest stabilizing force in a community." The authors rightly raise the question whether the present day graduate exerts the same desirable beneficent influence in the modern urban industrial community of which his highly specialized functions are a part.

Doctor in the Making is a valuable contribution not least because of its challenge to greatness in the physician of tomorrow.

Physiological Principles in Treatment By Sir Walter Langdon-Brown M.A. M.D. Hon. D.Sc., Consulting Physician to St. Bartholomew's and the Metropolitan Hospitals London and Reginald Hilton M.A., M.D. F.R.C.P. Physician to St. Thomas's Hospital London. Eighth edition. Cloth Price \$3.50. Pp. 323, with 4 illustrations. Baltimore: William Wood & Company, 1943.

The fact that this book has gone into the eighth edition would lead one to believe that it must be exceedingly valuable. Actually, after dipping into the text one wonders if the main reason the book has sold so well is that so many physicians are hungry for knowledge about modern physiologic principles in treatment. Most of the chapters are inadequate, much of the treatment advised is empirical and not based on any physiologic knowledge or thinking, and much is outdated. Thus, one finds under treatment of cholecystitis "A useful routine measure is to give 5 to 10 minims of belladonna to dilate the bile passages and 10 grains of salicylate of soda to dilute the bile, together with 10 grains of hexamine as an antiseptic, and 20 grains of bicarbonate of soda to prevent urinary irritation." Granting that any of these drugs could accomplish any of these things, which is extremely doubtful, how could the changes effected influence a disease which is usually deep in the wall of a gallbladder which commonly has no bile going in or out of it? Still more astounding is the recommendation that antiphiogistine be applied over the gallbladder! Turning to the extremely inadequate section on gastroenterostomy one is astounded to learn that "many neuroses are frequent sequels to the operation." Pernicious anemia has occurred too often to be explained as a mere coincidence! Evidently the writer had a dim recollection of Hartman's 1 case of hyperchromic anemia following resection of a stomach. Certainly it would seem that those who propose to teach ought to be somewhat up to date and fairly well informed.

Principles of Orthodontics By J. A. Salzmann D.D.S. Head Dental Service New York City Vocational Schools New York. Fabrikoid. Price \$10. Pp. 674 with 450 illustrations. Philadelphia: Montclair & London: J. B. Lippincott Company 1943.

To the orthodontist this book is disappointing as so little space is devoted to the science and practice of orthodontia and so much to preliminary topics of growth and development of bone, muscle, dentition and tooth eruption. Endocrine function and dysfunction, nutrition and diet have a relationship to dentofacial deformities, though they may be hereditary, environmental or acquired through illness and sometimes accentuated through habits.

Classification and diagnosis of dentofacial anomalies are determined according to different standards. Angle, Simon and Hellman reach their conclusions, determining the deviations from the normal standard, by different methods, which are described in detail. Pont has compiled a table of arch widths based on teeth widths. Thus by the use of the Pont normal tooth index the approximate amount of change required in the arch may be mathematically computed.

In addition to corrective orthodontic appliances, exercises are often prescribed to aid muscular development in forming a better facial contour. Schwarz classifies orthodontic pressure in four degrees, giving results under each degree, with warnings of resulting injury under too great stress. After orthodontic correction is completed retention is but "a leveling off of what we have been doing during treatment." Orban advocates that retention appliances should be worn until the internal transformation of the static jaw structure and the soft tissues is completed.

A complete bibliography makes this book valuable to the student as a reference guide.

Cancer of the Uterus By Elizabeth Hurdon C.B.E. M.D. Cloth Price \$5. Pp. 188 with 29 illustrations. New York & London: Oxford University Press 1942.

This book deals with cancer of the uterus. The author, Elizabeth Hurdon, was preeminently fitted for writing it, a task which occupied the last two years of her life. Prior to her death in January 1941 Dr. Hurdon entrusted the manuscript to the hands of her associates Drs. Martindale and Russ, who completed it for publication. The sixteen chapters deal with all phases of the subject, including incidence, etiology, pathology, diagnosis, prevention, treatment, complications and results. The clinical and pathologic material of the Marie Curie Hospital of London forms the basis of this treatise. An analysis of the hereditary histories of patients with uterine cancer at the Marie Curie Hospital was inconclusive. The author states that radiotherapy to a great extent has now replaced the surgical treatment of cancer of the cervix and she quotes statistics from the world literature on this point. There is a comprehensive discussion on the principles, technique, complications and results of radiotherapy of cancer of the cervix. Of 836 patients with cancer of the cervix given radiotherapy in the Marie Curie Hospital in London, 36.2 per cent were free of disease at the end of five years. The five year cures were 80 per cent in stage 1, 61.5 per cent in stage 2, 31.4 per cent in stage 3 and 7.2 per cent in stage 4. The radiation treatment of cancer of the cervical stump is discussed, also the surgical and radiation treatment of cancer of the body of the uterus. Cancer of the vagina, cancer of the vulva and the treatment of uterine hemorrhage in nonmalignant disease are discussed in the last three chapters. This is an excellent book. The presentation is sound and correct. It is a highly practical and important contribution to the literature on cancer of the uterus and is recommended as a useful guide to all who are interested in this subject.

Lehrbuch der allgemeinen Kinderpsychiatrie einschliesslich der allgemeinen Psychiatrie der Pubertät und Adoleszenz Von M. Tramer Dr. med. et phil. Priv.-Doz. der Universität Bern. Paper Price 26 Swiss francs. Pp. 485. Basel: Benno Schwabe & Co. Verlag, 1942.

This is a comprehensive textbook on child psychiatry. The author is a Swiss psychiatrist. He makes it clear that child psychiatry must not be narrowly conceived of as pertaining mainly to major mental illnesses but includes the study of all manner of difficulties, inhibitions and disturbances in psychologic development of the child. He characterizes his point of view as an anthropobiologic one, stemming from the teachings of von Monakow and akin to the psychobiologic approach of Adolph Meyer with its emphasis on envisaging the child "as a whole."

The author presents an orienting survey of the various psychologic approaches to the mental life of the child and discusses "normal physical and psychologic development. In investigative methods are outlined briefly. In his approach to general psychopathology, a developmental point of view is consistently maintained with emphasis on deviation in tempo."

development and in structure. Individual developmental deviations are presented in extenso under such categories as instinct drive feeding intelligence will character and temperament. Individual disturbances and illnesses are classified as somatic somatopsychic psychosomatic and psychic. Somatopsychic disturbances (e.g. syphilis and other nervous system involvements) are those in which the somatic factor is the prominent or determining one. The term psychosomatic is used in a narrower sense than in America primarily referring to psychoneuroses with physical symptomatology. In an appendix 25 illustrative clinical cases are presented.

This comprehensive work has much to recommend it. The attempt to envisage disturbances in childhood in relation to normal processes of growth and development is sound. A real attempt is made to evaluate and give proper emphasis to somatic, psychologic, social and other environmental factors in mental health and illness. The book is weak, however, in the intentional neglect of psychologic dynamics in favor of a descriptive point of view. The author here avoids some controversial issues but fails to give essential insights into many disturbances. Therapy despite a chapter on forms of therapy is on the whole rather neglected. The author's method of classification deserves attention. The book as a whole despite the serious limitations noted is a distinguished accomplishment and should be available in all medical school libraries.

Your Child, His Family and Friends. By Frances Bruce Strain. Cloth. Price \$2. Pp. 216 with 12 illustrations. New York and London: D. Appleton Century Company, 1943.

This book like so many others of recent date was written for parents of young children. In a light vein the author gives advice and records her own observations on juvenile behavior. As war activities increase many homes will be affected—the relationship of parents and their children will change. Nursery schools, after-school centers will gain in importance. The author attempts to explain the mechanisms which govern the child's emotional development and the conduct of manifestations which often follow when he has suffered faulty guidance (a rather large order). Toughness in dress, speech, radio programs and motion pictures are the orders of the day. Every real man must be either tough on the outside and tender within or vice versa.

Parents should prepare the child for what he is to expect whether he goes to church, school, doctor, hospital, dentist or barber. Adults who achieve economic success, marital harmony, social adaptation, personal accomplishment, and those who fail may find the explanation in the emotional experiences of childhood. Sex education is treated in a chapter on new brothers and sisters. The book contains a lot of good advice.

The Inner Ear Including Otoneurology, Otolaryngology and Problems in Modern Warfare. By Joseph Fischer, M.D., Staff Member, Beth Israel Hospital, Boston, and Louis E. Wolfson, M.D., Instructor in Ear, Nose and Throat, Tufts Medical School, Boston. Cloth. Price \$5.75. Pp. 421 with 77 illustrations. New York: Grune & Stratton, 1943.

Griffith in 1924 in reviewing the history of vestibular equilibration pointed out among numerous other things that it was Flourens over a hundred years ago who first demonstrated that excitation of the semicircular canals of the internal ear produced effects similar to some obtained by certain types of cerebellar stimulation. A close connection between function of one part of the inner ear and the cerebellum was thus pointed out and in the succeeding years the nonacoustic function of the inner ear was solidly established. From the time of Flourens until the present a great deal of investigation has been carried out. Barany through his work in the first ten or fifteen years of the present century excited the imagination particularly of otologists. The number of physiologists and clinicians before and since Barany's time whose ardent labors produced some understanding of the mechanism of the end organ and its central connections in health and disease are legion. Griffith mentions no less than 1701 separate references to the literature from 1820 to 1921, and there has been much work done since then. To assess this enormous material properly to choose what is lasting and important and to combine properly the theoretical and the practical have been the task of the authors of this textbook. Thus they have done remarkably well and the clinician finds for the first time perhaps so well done in English an introduction to a field of great interest and complexity.

There is a beginning chapter on clinical anatomy. It is well illustrated and is followed by a dissertation on the general physiology of the static labyrinth which is followed by a chapter on applied physiology. To avoid confusion the authors have discussed almost every topic twice. In chapters on physiology theoretical considerations are handled and in the portions devoted to functional tests clinical techniques and practical aspects are stressed. There follow illuminating discussions of inflammatory diseases of the inner ear and their intracranial complications as well as more than passing attention to such topics as facial palsies, inflammations of the petrous pyramid, congenital diseases of the inner ear and the neoplasms of this region. The need of otologists for a book of this character has been apparent for a long time. The authors are to be commended for filling this need so well.

Introduction to Psychiatry. By W. Earl Biddle, M.D., Senior Physician, Warren State Hospital, Warren, Pennsylvania, and Mildred van Sickle, B.S., R.N., Instructor of Nurses, Warren State Hospital. With a foreword by William C. Sandy, M.D., Director, Bureau of Mental Health, Pennsylvania Department of Welfare. Cloth. Price \$2.75. Pp. 358 with 38 illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

This work by the senior physician and the instructor of nurses of a large state hospital offers an excellent introduction to psychiatry for nurses, nursing attendants and others having to do with the care of mentally ill in institutional settings. It is a very practical work attempting to make clear just what a nurse or attendant will encounter in a hospital setting. The meaning of the situation to the patient, care of the patient and the handling of special problems such as destructiveness, suicidal attempt and aggressiveness toward others are discussed. Psychiatric disorders with illustrative cases are outlined. Chapters on legal considerations and on prevention of mental disorders round out the discussion. The book meets excellently the purpose for which it was written. It is much too elementary and sketchy to be useful to the student of medicine but the introductory material it offers is sound and could well be required reading for attendants and others who must have contact with patients in mental hospitals. An excellent annotated bibliography is provided. Questions at the end of each chapter are included as a teaching aid.

Laugh at the Lawyer Who Cross Examines You! A Court Room Anti-date. By Charles L. Cusumano, LL.B., of the New York Bar. Cloth. Pp. 375. New York: Old Faithful Publishing Company, 1942.

Many people, according to this author, who admits that he has writing on the brain prefer a dose of castor oil to an appearance in court as a witness. The oil may be gulped and the results are fairly predictable: the witness may gulp and swallow but is sure of nothing but perhaps a cold sweat. The purpose of this book is to convince potential witnesses that after all an appearance in court need not be a nightmare if proper preparation has been made and if certain fundamental rules are understood and followed. These rules, which are described as rules of experience are set forth by the author and developed in detail. Some seventy-five pages are devoted to expert witnesses in general, twelve pages of which are concerned with the medical expert. The reviewer has read the book with mixed emotions. There is much in it that can be recommended, its facetious style, however, may not wear well with many readers.

Spectrophotometry in Medicine: Being the Authorized Translation of "Medizinische Spektrophotometrie." By Priv.-Doz. Dr. Ludwig Hellmeyer. Translated by A. Jordan, M.B., B.S., D.Sc., Junior Demonstrator in Chemical Pathology to St. Bartholomew's Hospital, London, and T. L. Tippell. Cloth. Price \$6.75. Pp. 280 with 120 illustrations. London: Adam Hilger Limited, 1943.

The theory and selected methods of absorption spectrophotometry and their application to studies of whole blood, serum, urine, bile, ascitic fluid and cerebrospinal fluid are discussed in this volume, which presents an excellent survey of work in this field up to 1932. The book is well illustrated with charts and tables detailing quantitative aspects of the absorption spectrums of many naturally occurring pigments in normal and in pathologic conditions. Of particular interest are descriptions of the König-Martens spectrophotometer and the Zeiss-Puffrich step photometer and the discussions or supplementary photographic procedures for spectrophotometry and the earlier photo-

electric spectrophotometric methods of Suhrmann and Kollath and of Warburg and Negelein. In the eleven years since the publication of the original volume, from which this book is a translation, practical quantitative absorption spectrophotometry has become an increasingly important research tool. Many advances have been made possible by the introduction, improvement and increased production of spectrophotometers suitable for use in the ultraviolet and visible regions of the spectrum. Much of this progress is not reflected in the present volume. However, since the intelligent use of a physical method requires familiarity with the principles involved, a knowledge of the scope of prior applications and an appreciation of the practical limitations of the method, this book should prove of value to students and to workers in the field.

The Practice of Refraction By Sir Stewart Duke Elder M.S., D.Sc. M.D., Surgeon-Oculist to H.M. the King. Fourth edition. Fabrikoid. Price \$1.50. Pp 328, with 183 illustrations. Philadelphia: Blakiston Company, 1943.

This edition of Duke-Elder's popular textbook on refraction was necessitated by the demand, but, as the author says in the preface, "Few changes have been made in this new edition, which retains the essential character of its predecessor, a circumstance rendered imperative owing to the exigencies of military service." For those who do not know the earlier editions, it may be repeated that this is a comparatively short textbook that presents the subject of the correction of defects of the optical system of the eyes and the associated muscles in a practical manner. Theory and mathematics have been eliminated as far as possible and stress has been laid on clinical practice. Consequently it is an ideal book for the student and beginner in ophthalmology, but at the same time it contains the summation of so much clinical experience that the trained ophthalmologist can profit materially and enjoyably by a study of these pages, written with the flowing ease of which Duke-Elder is a master.

Textbook of Medicine By Various Authors. Edited by J. I. Conybeare, M.C., D.M., F.R.C.P. Physician to Guy's Hospital. London. Sixth edition. Fabrikoid. Price, \$7.50. Pp 1147. Baltimore: William Wood & Company, 1942.

The first edition of this well known British textbook of medicine appeared in 1929. The editor has encountered more than the customary difficulties of compilation because of the wide separation of the contributors because of the war and the rapid progress of development along some lines. The sections on tropical diseases and vitamin deficiency diseases have been entirely rewritten. Other sections have been revised more or less extensively. By a great effort the size of the book has been immaterially changed. This has been facilitated by avoiding almost all references to men or publications. Textbooks such as this are still in wide use by medical students and physicians.

Researches in Clinical Physiology By Sir Almroth E. Wright M.D. F.R.S., Director of the Inoculation Department and Principal of the Institute of Pathology and Research, St. Mary's Hospital, London. Researches from the Inoculation Department, St. Mary's Hospital. II. Cloth. Price 12s 6d. Pp 163 with 2 illustrations. London: William Heinemann Medical Books, Ltd. 1943.

This little book contains reprinted articles by Sir Almroth Wright published between the years 1891 and 1905. The papers deal with various subjects such as the pathology and therapeutics of scurvy, problems of the coagulability of the blood, the causation and treatment of thrombosis, and hemophilia. As most of these papers are now mainly of historical interest a detailed review is unnecessary. For the same reason the book will be of limited interest.

Facts for Childless Couples By E. C. Hamblen M.D. Associate Professor of Obstetrics and Gynecology. Duke University School of Medicine, Durham, N. C. Cloth. Price \$2. Pp 103 with 11 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas. 1942.

This is a well written book containing a carefully presented analysis of the factors that may combine to produce sterility. Its contents include a chapter on the general considerations of childlessness, followed by chapters explanatory of the reproductive functions of the husband and wife, on examinations of the husband and wife to determine the cause of childlessness, on what treatments of the husband or wife may be necessary, on

the probability of success of such treatments, and a concluding chapter dispelling some popular misconceptions about sterility and about the correction of that condition. The foreword correctly states that the book will be of special value to the childless couple. It can also be read with advantage by physicians to whom childless couples may appeal for help.

Nutrition and Diet in Health and Disease By James S. McLester, M.D., Professor of Medicine. University of Alabama, Birmingham. Fourth edition. Cloth. Price \$8. Pp 849, with illustrations. Philadelphia & London: W. B. Saunders Company, 1943.

The speed of intensive research on nutrition is reflected in the new edition of McLester's standard work. It has been necessary to rewrite entirely the chapter on vitamins, the nomenclature is revised, and attention is called to many new products in this field. Much has been added about mineral elements. The food allowances constructed by the Food and Nutrition Board of the National Research Council and a copy of the table are included, and also such activities as the movement for enrichment of flour. Statements are made about dehydration, storage and other modern methods of processing food. A special section has been added on nutrition in the aged and on nutrition in industry. These new sections help to make even better a book which has been recognized among the best in its field.

Handbook of Health for Overseas Service By George Cheever Shattuck, M.D. and William Jason Mixer M.D. Second edition. Cloth. Price \$1.25. Pp 228 with 15 illustrations. Cambridge, Massachusetts: Harvard University Press, 1943.

This handbook is intended for use by people who may be unable to obtain medical advice. It is revised from the first edition. The first edition was financed by the Office of Coordinator of Information and was distributed to those overseas who required it. The present edition is published by the Harvard University Press. The subjects of the chapters are keeping fit, common ailments of worldwide occurrence, the tropics, diseases important in the tropics, biting insects, vermin and snakes, the arctic, surgery, first aid and miscellaneous medical information. An appendix includes instruction regarding packing medical and surgical equipment, and tables of weights and measures. All together this is a most practical and useful little book.

New Aspects of Cheap Food By Rudolph Keller D.Sc. Paper. Price, 1s 6d. Pp 52. London: Research Books Limited in Association with William Heinemann (Medical Books) Limited, 1943.

This pamphlet is apparently intended to introduce continental ideas of diet and cookery into England. As such it has little interest for the American reader, either professional or lay. Its basis table of food values, in terms of so-called multiples against potatoes, takes into consideration nutritional contributions by price, thus for example white bread, on the basis of its contribution of carbohydrates, protein, fat and calories per ounce, is estimated as 2.9 against potatoes and on the basis of price is equivalent to 0.9 unit of potatoes. The author is a strong supporter of the European school of thought which holds that too much sodium and not enough potassium enters into the diet of the human race.

A Guide to the Prevention of Weight Lifting Injuries United States Department of Labor Division of Labor Standards. Special Bulletin No 11. Paper. Price 10 cents. Pp 20 with illustrations. Washington D. C. Supt. of Doc., Government Printing Office, 1943.

The United States Department of Labor has just made available this simple guide. Statistics from three leading industrial states show that sprains, strains and hernias constitute one fourth of industrial accidents. Moreover, about one half of these may be attributed to lifting and carrying weights. The excellent pamphlet discusses the causes and the elimination of the hazard and describes fully safe carrying practice. There are many excellent illustrations.

Facts About Child Health 1943 U. S. Department of Labor Children's Bureau Publication 294. Paper. Price 10 cents. Pp 16. Washington D. C. Supt. of Doc. Government Printing Office 1943.

This pamphlet is a condensed outline of the work, the policies and the aims of the United States Children's Bureau and as such should be interesting and important reading for every physician, public health worker and informed citizen.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ROENTGEN TREATMENT OF AMENORRHEA AND STERILITY

To the Editor—A patient complains of sterility which has been traced to the presence of anovulatory amenorrhea. Treatment with hormones has been unsuccessful and x-ray treatment has been advised. Kindly let me know the present status of treatment of this type of sterility in particular by x-rays. I am particularly interested in knowing the approximate number of cases treated to date, the approximate percentage of success taking into account the average period of sterility before treatment was started and also the incidence of any harmful effect of the treatment on the mother or unborn child. M.D., New York

ANSWER—The immediate results of roentgen treatment of amenorrhea and sterility are excellent. Kaplan (*New York State J. Med.* 39 1380 [July 15] 1939) treated 142 patients and menstruation was reestablished in 124. In 52 of these women subsequent pregnancy occurred and in this series 17 women conceived more than once. Forty-four women went to term and delivered 50 normal babies. Five women had abortions. Mazer and Baer (*Am. J. Obst. & Gynec.* 37 1015 [June] 1939) observed restoration of menstrual function in 59 per cent of 106 cases of amenorrhea treated by low dosage irradiation of the pituitary gland and ovaries. Twenty women gave birth to healthy babies and 4 had abortions. Mazer and Baer reviewed the literature on the statistics of roentgen treatment of amenorrhea and the results in most cases were encouraging. A survey of the literature revealed no ill effects on the offspring following preconception irradiation within the limits of dosage employed in this type of therapy. The usual number of abortions is within the usual average incidence. Even heavy preconception irradiation of human ovaries was found to have no harmful effects on offspring of the first generation. However, as Mazer and Baer remark, the problem of damage to human germ cells by heavy irradiation still lacks the necessary fundamentals for proper solution, but this problem does not apply to the small doses employed in the treatment of menstrual disorders. Nevertheless these authors admit that the margin between a safe and a harmful dose is probably limited.

Not all authors agree on the harmlessness of irradiation of the pituitary gland and ovaries. Greenhill (1937 Year Book of Obstetrics and Gynecology, p 666) says "The feeling about the use of x-ray treatment to overcome amenorrhea and sterility is somewhat analogous to the sentiment about irradiating the pituitary gland to combat menopausal symptoms. Those who favor x-ray treatment are most enthusiastic about it, but a large proportion of those who do not use this treatment condemn it in no uncertain terms. One thing is true, there is no apparent immediate harm from x-ray treatment in most cases although sometimes permanent amenorrhea occurs. Whether any remote adverse effects will appear from such treatment is theoretical. Of course, only a skilled roentgenologist should be called in to treat women who want to overcome sterility and amenorrhea." Subsequently Greenhill (1939 Year Book of Obstetrics and Gynecology, p 402) says "I wish I could be as confident as Kaplan of the innocuousness of radiation therapy to the offspring of women who have been subjected to this form of therapy. The results of roentgen treatment in cases of amenorrhea and sterility are excellent and as far as we know the treatment of the women is harmless in most instances. However, what may happen to the offspring is not definitely known. While it may be fallacious to reason that what occurs in animals necessarily must take place in human beings, we must nevertheless not disregard animal physiology and pathology. In fruit flies, mice and guinea pigs abnormalities appear in the offspring after irradiation but the disturbances usually do not manifest themselves until the third generation, that is, great-grandchildren. Since roentgen therapy has not been used for more than thirty years, we do not know what will happen to the great-grandchildren of women who have received deep x-ray treatment. Perhaps we will find that the animal experimentation dealing with roentgen treatment may be applicable to human beings. It may be found that whereas the children and perhaps even the grandchildren of women who were subjected to x-ray therapy were entirely normal the subsequent progeny was detec-

tive either anatomically or physiologically or both. Numerous authorities believe in the possibility of harm of radiation therapy. Among them are H. J. Muller (the first investigator to discover the harmful effects of irradiation), J. H. Mueller, Timofeev-Ressovsky, Little, Bagg, Martius, Peckham and I. Seth Hersh. Those interested in this subject should read a short article by I. H. Mueller entitled "The Use of Radium and Röntgen Rays in Gynecology in the Light of Genetic Radiation Research" (*Schweiz. med. Wochenschr.* 69 849 [Sept 23] 1939).

Since the immediate results of radiation therapy are good and since it has not yet been proved that harm may result to the human offspring, it may be justifiable to apply this therapy to some women who are anxious to have a child. However, the possible theoretical dangers should be explained to both husband and wife and the final decision left to them.

The technique advocated by Kaplan is as follows: Factors used are 200 kilovolts, 4 milliamperes with 0.5 mm of copper plus 1 mm of aluminum filter, target distance 30-40 cm. Treatment is directed through anterior and posterior right and left pelvic fields of 9 by 12 to 10 by 15 cm and to the pituitary area on the skin through a 6 by 8 cm field. Dose given is 75-100 roentgens per field at weekly intervals for three weeks. The anterior pelvis is treated the first week, the posterior the second and the anterior again on the fourth week. Occasionally a fourth treatment is given. The pituitary is treated at the same session as the anterior pelvis.

The treatment recommended by Mazer and his associates is 135 kilovolts, 5 milliamperes at a distance of 40 cm with 6 mm of aluminum filtration through a field of 20 by 20 cm. The rays are directed over the anterior pelvic area. Depending on the thickness of the pelvis, 60 to 90 roentgens is given to the skin. This is repeated at intervals of one week three times. The total dose reaching the ovaries is about 10 per cent of a full skin erythema. The pituitary gland is treated with the same dosage and factors through a field 3 by 3 cm simultaneously.

CHRONIC NONSPECIFIC URETHRITIS

To the Editor—A single white man aged 34 gives a history without record of venereal diseases or urethral discharge. The Wassermann reaction is negative. He has had sexual contact with one person for several months and has not used a prophylactic. Eight days after and sixteen hours after the last two exposures respectively he noticed a small amount of grayish white mucoid discharge appearing at the external meatus. This did not drip but came almost to a drop when the urethra was stripped manually. The meatus would remain moist and stick to his undergarment. There was no burning, itching or frequency of urination. The urine in the first glass showed shreds and particles; the urine in the second glass showed only a few minute particles and no shreds. Five smears and two cultures were negative for the gonococcus. The prostate was not tender or enlarged. With the exception of a little low back discomfort and a tired painlike feeling down the inside of the left thigh region later on there were no other symptoms. He was given four courses of sulfathiazole (20 Gm for five day periods each time) without any improvement. This was given during the eight month period that the condition has been present. The urethra was irrigated with 1:5000 acriflavine six times, followed by mild protein silver (5 per cent) instillations into the bladder without any improvement. The patient continues well and does not complain except that this condition which has now existed eight months and shows no sign of stopping worries him. Can you tell me where the trouble is? Is this a nonspecific condition? What treatment can I render to clear this up? Can I be sure now that it is not gonorrhea? Why does it continue so long? Alcohol and sexual contact have no effect on it either way. M.D. New Jersey

ANSWER—There is little doubt that the patient is suffering from a nonspecific urethritis. The persistence of infections such as this is almost invariably caused by one of two conditions: there is either a chronic infection of the prostate and seminal vesicles or a stricture of the anterior urethra. The statement was made that the prostate was not tender or enlarged but what about the microscopic study of the expressed secretion? This, and only this, determines the status of these structures as a possible cause of the original complaint. One should calibrate the urethra carefully, watching for stricture of the anterior urethra especially; it is important to note the caliber of the external urinary meatus as a congenital stenosis here is commonly the cause of a nonspecific infection in the first place and it is equally responsible in its becoming chronic.

Obviously the management of such a chronic infection depends on the cause. A careful prostatic and seminal vesicle massage followed by an irrigation once a week and urethral dilation followed by an irrigation on the second week is a successful routine usually in the management of these conditions. If the external urinary meatus will not admit a sound of adequate caliber a urethral meatotomy should be done as a preliminary procedure. It is well likewise to give short intermittent courses of urinary antiseptics such as sulfathiazole.

GALACTORRHEA AND OBESITY

To the Editor—A woman aged 27, unmarried and a virgin, has had a milky discharge from both breasts during the past seven years. The details of her case are as follows. At the age of 20 she started training to be a nurse. In the six months after this her weight increased from 127 to 171 pounds (57 to 77 Kg), where it remained for four years. Her menses, which had been regular and painless but profuse, lasting seven days every twenty-eight days, did not appear for eight months, after which they lasted only three or four days each month and would occasionally be missed for three or four months. During the period of amenorrhea she several times noticed little damp spots on her clothes which appeared to be due to a milky discharge from the nipples. Then she noticed it no more until she was 24, when a milky discharge from the nipples came to be nearly always present, more from the right breast than the left, more in hot weather than in cold, more while she was doing hard work than while she was doing light work. For a time then the right breast was a little larger than the left, they had both become large when her weight increased. The milky discharge has persisted up to the present time. Her weight is now 192 pounds (87 Kg). The menses now last only two days and are scanty and sometimes absent for one or two months. She has never told any one of her symptom till lately. She is a bright healthy young woman who practices her profession on the staff of a large hospital. She has had no illnesses. Her mental outlook seems normal, but she is a little reserved and says that she has never had a particular boy friend. She supports a widowed mother but has no anxieties. Her obesity is general in distribution and does not suggest any particular endocrine disorder. Her skin is normal. The hair is feminine in type and distribution. The breasts are large and inclined to be pendulous. The areolas are pink, 4 cm in diameter and without large tubercles. The nipples are small but prominent and there is a discharge like colostrum from each, but only a few drops could be collected by expression. No other abnormality can be discovered on physical examination. An anteverted nulliparous uterus can be palpated by rectum. The external genitalia are normal and the hymen is intact. The blood pressure is 120/85. Diethylstilbestrol in doses of 5 mg daily has had no effect. M D, Australia

ANSWER—The milky discharge from the breasts, known as galactorrhea, is most likely due to hyperactivity of the anterior pituitary hormone prolactin. In rare cases this may be due to persistent, abnormal stimulation of the breasts but nearly always there is some disturbance in other glands of internal secretion. In this case the galactorrhea is undoubtedly linked with the menstrual disturbance and also with the obesity. First the thyroid function should be studied by repeated basal metabolism tests and blood cholesterol studies. If a thyroid dysfunction is found, it should of course be treated. Then a decided attempt should be made by the patient to reduce her weight. This will mean the development of a strong will power to curtail the amount and character of the food eaten. Since the menses now occur with a fair degree of regularity, even though they are scanty, no treatment need be directed toward it. Thyroid therapy alone may suffice to make the menses more normal and help the patient reduce her weight. In this event the secretion of milk may diminish or cease altogether. If not, an attempt may be made to depress pituitary activity by means of estrogens or androgens. If a sufficient amount of diethylstilbestrol fails to affect the flow of milk, the androgens may be tried. Twenty-five mg of testosterone propionate may be given intramuscularly three times a week for four weeks or longer. However, if more than 300 mg of testosterone is given, virilizing effects may appear, such as growth of hair on the chin and upper lip, change in voice and slight enlargement of the clitoris. Furthermore, even if the testosterone propionate brings about relief, its effect will usually be temporary, so that further courses of the androgen will have to be given.

VISCEROPTOSIS

To the Editor—The symptom complex of congenital visceroptosis is too well known to mention. I have a family as patients in which the daughter, aged 10, has the same physical build as that of her mother. Please give me an opinion as to the advisability of fitting this child with an uplift girdle. M D, Virginia

ANSWER—Inquiries of this nature are evidence of the fact that there are many physicians who still continue to diagnose and treat visceroptosis as a disease in conformity with the conceptions of Glenard (1885) and Stiller (1907). However, as the result of authentic clinical observations and anatomic research in the past thirty years, the profession has become more and more skeptical about the significance of visceroptosis, congenital or acquired, and even entertains serious doubts as to whether such diagnosis has ever been warranted. Such investigations seem to have reached their culmination in the work of Moody, Van Nuys and Chamberlain (*THE JOURNAL*, Dec 8 1923, p 1924) and of Moody (*J Anat* 61 223 [Jan] 1927). Draper and Touraine (1932), Alvarez (1931) and others have pointed out that exceptional athletic prowess and the asthenic habitus are not incompatible. Many patients are more comfortable

when wearing an abdominal support, especially those who have protuberant abdomens. Such improvement, whether real or apparent, is not so much attributable to elevation of the abdominal organs as to increased intra-abdominal tension and better support for the spinal column. Appliances directed to the treatment of "virginal ptosis" are particularly ineffectual and rarely indicated. An adequate amount of intraperitoneal fat furnishes an effective and permanent support for the viscera. Therefore proper dietary measures should be instituted with this in mind. If the abdominal muscles are flabby or undeveloped, abdominal exercises such as those outlined by Martin (*Surg, Gynec & Obst* 15 150 [Aug] 1912) usually prove helpful.

ADHERENT SCAR IN FRONT OF TRACHEA

To the Editor—A woman aged 40 with a history of a thyroidectomy fifteen years ago complains of difficulty in swallowing and of pressure in front of her neck. She shows in the center of her old scar right in front of the trachea a deep funnel shaped scar, which is adherent to the trachea. X-ray examination, bronchoscopy and esophagoscopy reveal no pathological changes. The patient's symptoms can probably be derived from the deeply situated scar. I intend to remove the scar and separate the adhesions between the skin and the trachea, but what can be done to prevent a recurrent adhesion? M D, Ohio

ANSWER—By all means this scar should be removed, including all the affected skin. If normal skin with subcutaneous fat is brought over the trachea, there is little likelihood of recurrent adhesion.

GLYCOSURIA IN DIABETES

To the Editor—It seems to me that the answer to the query entitled "Unclassified Glycosuria in Diabetes" (*The Journal*, July 17, 1943) is inadequate on three counts. 1. A diagnosis of probable diabetes is given on the basis of a dextrose tolerance curve (data in note) which appears to me to indicate a normal much more than a diabetic individual. 2. I consider his discussion of the renal glycosuria overcautious. 3. The suggestions tendered to the physician for confirming or discrediting a diagnosis of diabetes are rather incomplete.

The basic character of the patient's dextrose tolerance curve was a forty-five minute rise from a normal fasting blood sugar to a moderate height which was maintained as a plateau for a period of nearly two hours, whereupon a very sharp descent to a value below the fasting blood sugar occurred. It should be emphasized that, except for the overlong maintenance of a high plateau value, this is an essentially normal curve. The rise was fairly sharp, as was the descent. There was not a subsequent very slow but continuous decline to near fasting levels typical of a person with diabetes. The liver, of course, is the important organ in determining the level of the blood sugar, the role of insulin in this organ is not as distinctly understood. The work of Soskin has clearly demonstrated that one of the most fundamental effects of insulin in the liver is that it, in conjunction with the anterior pituitary hormone, establishes a distinct equilibrium point above which sugar is taken from the blood and below which sugar is released to the blood. Insulin may or may not play a role in the systems involved in the breakdown or synthesis of the metabolic systems involved in the breakdown or synthesis of glycogen by the liver. It is probable that it does. However, the essential fact is that insulin is the limiting factor in determining the equilibrium point, but there are a number of additional factors which may be involved in the systems which determine the rate of glycogenolysis and its reverse. Therefore the plateau observed is much reduced in significance because there may have been operating factors other than insulin which determined the length of time which was required before normal levels were reached. In this case excessive nervousness incident to the taking of the sample could easily have led to this prolonged plateau. The sharp return to a below normal level has far more significance.

As for the glycosuria, if the patient has the normal fasting blood sugar the data seem to indicate that there can be no question that it is due to either impaired renal function or a normal low renal threshold for sugar. I have seen persons who display renal thresholds to sugar of from 100 mg to 300 mg per hundred cubic centimeters. Further indication that the glycosuria is due most probably to a low renal threshold rather than a diabetic blood sugar is the fact that although the patient has had the glycosuria for fifteen years he has been in excellent health during this period.

It seems to me that in view of the indecisive nature of the evidence pointing to diabetes a few simple follow ups should be made which could go a long way in clearing up the matter. First, the patient's normal blood sugar level under various conditions should be determined. Second, the response of the patient to normal stimuli such as meals should be noted. Also, because of the inconclusive nature of the tolerance test recorded, several more should be made, including the Exton-Rose two dose test. Once the patient's normal blood sugar level has been determined, the question of the renal glycosuria is easily clarified.

VACCINE AND SERUM FOR ROCKY MOUNTAIN SPOTTED FEVER

To the Editor—In *Queries and Minor Notes* in *The Journal*, June 12, 1943, page 475, the statement was made, with regard to vaccine for immunization against Rocky Mountain spotted fever, that "one of the biological laboratories has been licensed to manufacture the egg vaccine but because of press of war work it is doubted that the material is commercially available at this time." The Lederle Laboratories have been distributing both Rocky Mountain Spotted Fever Vaccine (Cox type) and Anti Rocky Mountain Spotted Fever Serum since May 5, 1942. These products are hence commercially available. Frank C. Crompton, New York

THE UNFITNESS OF YOUNG MEN IN MOTOR FITNESS

THOMAS K. CURETON, PH.D.
URBANA, ILL.

The medical and public health reports¹ of the Metropolitan Life Insurance Company and the Medical Division of the Selective Service² do not indicate the extent of unfitness of young men in motor fitness but deal with the more general health aspects involving teeth, eyes, heart, ears, feet, lungs, hernia, musculo-skeletal defects and venereal diseases. Louis I. Dublin points out that the health of young men of the nation is better than ever on the basis of morbidity and mortality statistics. In the Navy, rejections have averaged 54.9 per cent and in the Army about 50 per cent. Colonel Rountree, in commenting on the situation, says that this constitutes a problem of national concern and importance. It should call for immediate investigation and a prompt remedy. However, there is another side to the picture which is overlooked in these medical reports but which is of primary importance to the immediate needs of the armed forces. This is the state of young men in the dynamic aspects of motor fitness. Before the facts uncovered in the University of Illinois survey are presented, it is important to clarify the logic of the important elements in motor fitness.

There is evidence to show that a large proportion of young men entering college from high school are unable to handle their bodies with the degree of efficiency needed in wartime. This situation reflects the protected softness of their lives and the inefficiency of educational programs to produce an acceptable level of motor fitness, due undoubtedly to inadequate time allotment, facilities and leadership as well as the types of program offered in the schools. In wartime, physical education is charged with preparing young men for hard physical work in industry or military service. Motor fitness may be demonstrated by means of stunts or performances with the body, thus showing that it can be controlled and balanced in various positions, that it is supple and normal in all major joints and that it is strong in the trunk and limbs, also that it is agile in climbing, jumping, crawling or dodging with speed, that it can develop a highly powerful effort if necessary and that it possesses stamina in a variety of endurance feats involving long continued effort and recuperation.

PRACTICAL EMPHASIS IN MOTOR FITNESS

Physical ability involving balance, flexibility, agility, strength, power and endurance in a variety of performances sums up to motor fitness. A bad gap or blind area of development in any of these aspects will result in physical inefficiency in a large number of related performances. Motor fitness emphasizes the more generalized gross and fundamental physical abilities which are dominated by development of the kinesthetic sense, muscular energy and suppleness of the tissues and joints, including the aspects which are basically involved in athletic or work skills with the big muscles of the body rather than the finer low energy precision skills. It means capacity to run, jump, dodge, fall, climb, swim, ride, lift and carry loads and endure long hours of continuous work.³

Balance represents neuromuscular control paralleling the development of the kinesthetic sense in acts of sitting, skating, riding, tumbling, walking logs or fences, skiing, dancing and a host of everyday skills. Many people are handicapped because they fall and get hurt at the slightest provocation: slip on a rug, slip in the shower or in the pool or tub or when they dismount from a moving vehicle. The greatest number of serious accidents are due to falls involving poor awareness of unsteadiness or lack of compensating control. Many adults cannot ride a bicycle, skate, swim or ski. They are unsteady in shooting or fall easily from moving vehicles. Some do not readjust quickly to experiences in which the body is turned or revolved. Balance in this sense is educable. It can be learned by gradual education of the kinesthetic sense in a variety of balance stunts. The more natural and important these are, the better, but good preliminary training is associated with any fundamental gymnastic program. Advanced tumbling and diving require superb development of this ability.

Flexibility emphasizes the ability to move easily in the full range of joint movements, to tuck up tightly, to bend easily at the waist, to twist the spine easily, to point the toes fully and to breathe deeply and fully without much extra effort. Good suppleness is a concomitant of gradual and thorough body conditioning. It usually indicates that the joints and muscles are free from abnormal "muscle bound" conditions due to injury or abnormal development. Many events require flexibility directly, such as hurdling, obstacles, running under low wires, crawling through culverts and small diameter tunnels, vaulting through the arms, jumping over a stick held in the hands, skinning the cat and fancy diving. Body suppleness also indicates roughly a type

Ed.* 40:66-67 (March-April) 1943.

of physiologic youthfulness, an important characteristic of tissues and healthy blood vessels. Many people are awkward because they lack flexibility. The old person walks jerkily, so may an injured athlete whose torn tissues have healed with adhesions. People with poor flexibility usually tire easily, have little grace in bodily movements and learn physical skills slowly.

Agility emphasizes the capacity for fast reaction in controlled nimble movements "rabbit-like" in action, and to move quickly, dexterously and easily. It implies ability to dodge a ball or a missile quickly, to spring quickly to the feet, to climb up a cargo net quickly, to weave through a maze of obstacles quickly, to vault fences or barriers quickly or to zigzag quickly in running from shell hole to shell hole, to get down and up quickly, to put on a life preserver or parachute quickly, perhaps to climb out of a burning plane quickly or to pull oneself into a lifeboat, to climb a rope onto a ship or to lower oneself by rope from a burning building, and to vault onto a horse or vehicle quickly. Quick and efficient control of the body in an emergency may save the life of one individual or many. One should be able to change one's position quickly to avoid capture, fire, flood, bombs, gas, shells or gunfire. Obstacles must be overcome, sometimes in a hurry. Speed and endurance in the fundamental locomotion efforts are first essentials.

Strength emphasizes the capacity of the hands, legs or trunk to exert great force. Strong hands and arms are important for grasping, lifting or pulling heavy or resistant objects, such as shells, equipment, a partner, a heavy rifle or a machine gun. Holding the whole weight of the body suspended from the hands is a severe test if any appreciable time is involved. Swinging on or climbing ropes requires great strength of the hands, arms, shoulders and the large depressor muscles of the chest and back. Strength of the feet and legs is also important to bear the body weight, armor, pack and any extra burden. Weak feet and legs are a great handicap in marching under load, in lifting an injured buddy for a carry to safety, for jumping, running, skating, sking or pushing a car out of the mud. Most of all the trunk is the base from which the arm and thigh muscles arise. It serves as a base to support forceful movements of the arms and legs. The muscles of the upper part of the back and chest pull the arms downward in chinning or climbing. The muscles of the buttocks give force to all locomotion efforts, as in cycling, running or jumping. The long back muscles hold the trunk upright and make it steady in pulling and pushing. The abdominal and thigh flexor muscles reinforce all kicking movements of the legs and sit up and leg lifting movements. A very weak person may not be able to sit up at all or lift the legs from the floor while lying on the back, or, again, he may be one who cannot chin the bar once or lift the equivalent of his own weight from the floor. A strong man can pick up a 200 pound deer, log or an injured man and put any one of these in a wagon.

Power emphasizes the capacity to release great explosive force to sudden violent efforts. Speed and force must be combined for maximum effect in a jump, sprint run, pole vault, baseball game or a grenade throw for distance. Usually the whole body is projected or some object is impelled by power transferred from the body.

Endurance is capacity for continuous exertion involving in the first minute or two severe depletion of the oxygen reserve and the development of oxygen debt with severe distress. This is usually overcome by

forced ventilation and adequate circulation of the blood. When relief comes, it is sometimes called "second wind." Local fatigue may develop in particular muscles, such as those of the feet and calves in hopping, or in the arms in chinning, without much effect in other parts of the body or in the general circulation. Circulatory (cardiac) fatigue may be due to long continued exertion for several minutes or hours. Cramps may develop or the control and rhythm of the movement may be lost. Ability to recuperate to a degree and continue to run, swim, climb a mountain or march under load are most obvious tests of endurance.

CLINICAL TESTS OF ILLINOIS STUDENTS

In 1940 a sample of 1,000 entering men students at the University of Illinois were tested on aspects of motor fitness with the following results:

- 13 per cent could not swim at all (across tank)
- 64 per cent could not swim 50 yards
- 31 per cent could not chin themselves once
- 25.9 per cent could not chin themselves five times
- 24.1 per cent could not jump an obstacle waist high
- 41.7 per cent could not skim the cat

Some 14.2 per cent were judged by instructors to have very poor (soft, flabby or undeveloped) physiques and 10 per cent had a very poor posture.

In 1941 it was decided to continue this testing in order to study the men as carefully as possible. A standardized chinning-dipping-vertical jump test⁴ was given to 3,099 men in the service courses in physical education. In this sample of university men some 620 men could not chin themselves more than 4.5 times, push up on the parallel bars more than 4.5 times or jump vertically more than 18½ inches above their reach. These standards are so low, as experts in physical education understand them, that the results were considered serious enough to warrant special effort to remedy the situation.

A voluntary physical fitness clinic was formed for men who scored in the lower 20 per cent on the test. Some 176 men were studied carefully in the clinic. The selection was entirely on the basis of the chinning-dipping-vertical jumping test, although all men had been approved for exercise by the health service department. About 20 per cent of the men were fat and soft—of the endomorph or endomedial class according to Sheldon's classification⁵. About 35 per cent of the men were of the ectomorph or ectomedial class by the same system. Only 1.18 per cent were judged as having a well developed mesomorphic type of physique. A general sample of the student population showed a much greater proportion of the more desirable body types: 21.18 per cent mesomedials compared to 8.33 per cent in the clinic, 32.36 per cent ectomesomorphs compared to 5.95 per cent in the clinic. The general university male population sample averaged 321.61 on the composite score of the Larson test compared to 213.08 for the clinic sample. This difference is equivalent to the difference between a 68 percentile rating on the test compared to a 7 percentile rating as an average for the clinic sample.

In the physical fitness clinic about 50 per cent of the men could not make a hard abdominal wall to resist a fist pushed into it by an examiner. On a physique rating scale giving A, B, C, D and E ratings some

⁴ Larson, L. A. A Factor and Validity Analysis of Strength Variables and Tests with a Test Combination of Chinning, Dipping and Vertical Jump. *Research Quarterly*, 11: 82-96 (Dec.) 1940.
⁵ Sheldon, W. H., Stevens, S. S. and Tucker, W. B. *The Atlas of Human Physique*. New York: Harper & Bros., 1940.

84.5 per cent of these men were rated below a B by the examiners who felt the muscles of the arms, chest, part of the back, buttocks, thighs and legs under contraction. Some 36.9 per cent of the men scored below 7.9 on the Schneider test for organic efficiency, being classified as functionally unfit on this test.

The clinic sample was given an inventory of motor fitness⁶ composed of thirty items in all with five items in each of the areas of emphasis on balance, flexibility, agility, strength, power and endurance. The results are given in table 1.

In endurance 72.50 per cent could not swim 440 yards, nor could 67.8 per cent chin themselves eight times or dip on the parallel bars eight times to meet the passing standard for the clinic. Some 46 per cent failed the mile run in seven minutes and 32.2 per cent could not hold their breath thirty seconds after running in place for sixty seconds.

In power 68.50 per cent could not run 100 yards in 13.8 seconds nor could 61.5 per cent jump 20 inches above their reach. Some 56.9 per cent failed in their attempt to climb the 20 foot rope in twenty-five seconds. 43.2 per cent could not put the medicine ball 34 feet and 37.35 per cent failed the standing broad jump at 6 feet 6 inches.

In agility 54 per cent could not vault a bar placed at chest height, or 4 feet 6 inches, nor could 39.1 per cent jump over a stick held in the hands nor could 32.2 per cent execute a running dive and roll to clear 5 feet between two lines.

In strength, 78.20 per cent could not do the extension press up with the hands straight forward from the shoulders and pushing up from hands and toes, nor could 78.2 per cent hold the feet off the floor for sixty seconds while sitting in the V sit position with the hands on the hips. Some 21.82 per cent could not do twenty leg lifts and twenty sit ups in succession.

In flexibility 67.7 per cent did not possess as much vital capacity as the average standard for men of the same surface area, corrected for temperature. Some 11.5 per cent could not touch the floor with their finger tips while keeping the knees straight throughout a slow forward trunk bend.

In balance 95.40 per cent could not do a hand stand nor could 52.30 per cent do a squat stand for ten sec-

TABLE 1—Results of Tests

Endurance	45.35 per cent efficient
Power	46.51 per cent efficient
Agility	63.28 per cent efficient
Strength	67.14 per cent efficient
Balance	67.64 per cent efficient
Flexibility	74.97 per cent efficient

onds. Some 10 per cent could not do a 1 foot toe balance for ten seconds with the eyes open.

These facts, showing the men to be very deficient in many aspects of motor fitness, paved the way for the adoption of a universal motor fitness test required of all men students in the University of Illinois in 1942. A motor fitness test was devised using the best two items in each of the foregoing categories for balance, flexibility, strength and power and three items in agility and endurance.

ILLINOIS MOTOR FITNESS SCREEN TEST

It was impossible to test a very large sample with the thirty item inventory because of the large amount of time required with the staff available. Some simplification was needed but something more inclusive than the chinning-dipping-vertical jump test. The three item test correlated 0.447 with the 30 item criterion by direct correlation of total scores on each. A multiple

TABLE 2—Classification of Motor Fitness of University of Illinois Men

Total Scores	Frequency	Percentile	Rating
0	—	0	Poor
1	16	0.34	
2	20	0.63	
3	61	1.01	
4	71	2.51	
5	121	3.73	
6	143	3.73	Below average (fair)
7	19	12.71	
8	217	17.37	
9	203	27.27	
10	407	31.30	Average
11	61	41.45

14	6363	100.00	
Number of students 4392			

R of 0.548 was obtained by combining chinning, dipping and vertical jumping to predict the criterion of thirty items. Some screen test was needed which would correlate much higher than this. A combination of frog stand, trunk extension, flexibility, dive and roll, extension press up, medicine ball put and chinning combined by multiple regression technique to predict the criterion with a multiple R of 0.672 using the item in each major category of emphasis so that balance, flexibility, agility, strength, power and endurance would be represented. With the two best items from each category and the addition of foot and toe balance, vital capacity, residuals, bar vault, dynamometer strength, standing broad jump and mile run gave 0.860. A battery was finally arranged of fourteen items which correlated 0.872. The battery was called the Illinois Motor Fitness Screen Test. It has a reliability of 0.912 by correlating the scores made on successive weeks under the same conditions. The reliability of the individual items ranges from 0.87 to 0.95. When administered properly the items are relatively stable measures of ability, as the total gain in composite scores is only 0.63 point out of 14 as an average in the tests in successive weeks. However the items are improvable in a semester of training with greater percentage of improvement usually recorded in the balance and endurance items and least in the power items. The total scores improve from 23 to 40 per cent, depending on the time and intensity of training. The correlation between attendance and improvement is 0.444. The test has been normed for University of Illinois men with the results shown in table 2 (4392 cases tested in May and September 1942).

For screening purposes, when it is desirable to identify or "screen out" the lower 20 or 30 per cent the result may be controlled very well in a large sample. The distribution in table 2 shows that passing ten items would result in sectioning the lower third of the whole sample. In practice the standards have been made slightly harder than the distribution given, because after the first introduction of the test men will train for the test. The "passing" standard at the University of

6. Classification in Motor Fitness in Physical Fitness Workbook, pp. 37-52. An Inventory and Screen Test of Motor Fitness for High School and College Men. Physical Educator of the Phi Epsilon Fraternity, January, 1943.

Illinois is eleven items, including one endurance item, plus a rating above 3 in physique, and swimming ability for 75 feet.

The test is fundamentally arranged to differentiate the ability of the men into three groups according to their need for motor fitness conditioning.

1 Basic (poorest 30 per cent), failing to pass eleven of the fourteen items, or failing to pass one of the three endurance items, getting a physique rating of below 4 out of 10, inability to swim 75 feet over deep water.

2 Restricted (middle 30 per cent), failing to pass eleven items including two endurance items, getting a physique rating below 5, inability to swim 100 yards.

must take beginning swimming. Those with physique ratings below 5 because of poor musculature or posture are allowed to choose from apparatus stunts, weight lifting, individual tumbling, double tumbling, boxing and wrestling. Those who have physique ratings below 5 because of being too fat or because they failed the mile run are allowed a restricted choice from soccer, individual athletics, touch football and ice hockey, six-man football, military athletics—all vigorous running activities with considerable endurance work involved.

Students in group 3 are allowed to choose any course they like including some of the more socialized courses of dancing, bowling, badminton and tennis.

UNIVERSITY OF ILLINOIS MOTOR FITNESS TEST

University of Illinois motor fitness tests

3 Satisfactory (upper 40 per cent), passing eleven items including three endurance items, 7, 12 and 14 in table 3, rating above 5 on physique and ability to swim 100 yards.

Students in group 1 are assigned to especially arranged conditioning classes (P E M 60, basic physical fitness). They follow a graduated syllabus of work and maintain records of their physique, organic capacity and motor ability. These are kept in a physical fitness workbook which provides a guide for them to follow in the work.

Students in group 2 are allowed a restricted choice of course for physical education. They must select a course from a group which is known to have vigorous conditioning value. Those who do not swim 100 yards

The results on the screen test are quite satisfactory for differentiating ability and as a basis for assigning physical education classes. The test aims to identify the poorer ones in the lower 20 or 30 per cent so that they may be grouped for special instruction and better supervision than is usually provided. Individual conferences and guidance take more time and instructors with experience

ANALYSIS OF MOTOR FITNESS OF 2,628 YOUNG MEN

In September 1942, 2,628 entering men into the University of Illinois were tested, fresh from the high schools of Illinois and nearby states. The gross classification resulted in 35.84 per cent being classified in the basic group, failing to pass the test, 23.71 per cent were

put into the restricted group as near failures 40-45 per cent were rated satisfactory. The results are shown in table 3.

The results are rather startling because among the 35.84 per cent who failed to pass the test the proportion of failures on the fourteen items is so high that concern should be manifested for the physical and health future of the men. For instance 79 per cent could not hit the legs from the floor twenty times while lying on the back and then do twenty sit ups in succession. This standard is not very high because a fit man can do as many as 100 leg lifts and two hundred to five hundred sit ups. Some 78.8 per cent could not chin themselves ten times in succession and 76.1 per cent could not jog a mile in seven minutes a very mediocre performance for any one who has the ability to run the distance. The organic capacity must be low in these cases, and the Schneider test scores for these failures in the mile average about 7 (functionally inefficient). Table 3 gives the results for all fourteen items in the three classes of satisfactory, restricted and basic. The results show that very large percentages of men fail relatively low

if all men in both groups pass it. It is a good item only as the percentage of failures is definitely greater in the poorer group. This might be shown more exactly with bilateral correlations between the total scores and the pass and fail responses on any item. It is obvious that a test with only a few items does not adequately test the ability in enough fundamental qualities and is apt to miss the point if applied to the low tail of the distribution curve. The screen test used in this work has been made to do just what it does very well—separate the poor men from the better ones at the 20 to 40 percentile level of ability.

The results are quite stable as the ranks of the items according to relative difficulty rating correlated 0.92 in two samples taken in July and September 1942 with different men involved.

RESULTS IN SWIMMING ABILITY

In the September 1942 data there were 2,557 who responded to the swimming questionnaire. Responding that they could not swim 'at all' were 679 men or 26.55 per cent. Stating that they could swim 75 feet

TABLE 3—Results of Motor Screen Test—Analysis of Failures

Item Number	Area of Emphasis	Name of Item and Standard	Number and Percentage of Failures on Each Item							
			Satisfactory		Restricted		Basic		Total	
			Number	Per Cent	Number	Per Cent	Number	Per Cent	Number	Per Cent
1	Balance	Foot and toe balance 10 seconds each	42	4.0	34	5.5	161	17.1	237	9.6
2	Balance	Squat stand on hands 10 seconds	136	19.8	128	20.6	513	54.5	777	29.9
3	Flexibility	Trunk extension, 20 inches	10	10.0	103	16.5	223	23.7	436	16.4
4	Flexibility	Trunk flexion 6 inches	169	17.8	155	24.9	47	5.6	371	14.2
5	Strength	Extension press up once 4 inches	248	23.3	215	34.5	671	71.2	1,134	44.1
6	Strength	Man lift and let down once own weight	73	2.9	11	3.4	163	17.2	247	9.5
7	Endurance	Leg lifts and sit ups 20 each in succession	208	28.0	324	52.0	744	79.0	1,276	50.0
8	Power	Medicine ball put 35 feet	89	8.9	90	14.5	435	46.2	614	23.9
9	Agility	Running dive and roll 6 feet (or agility run)	85	9.0	145	23.3	380	62.5	610	23.1
10	Strength	Skin the cat hips one foot below shoulders and back	83	7.8	98	15.7	609	64.7	790	30.5
11	Agility	Bar or fence vault 4 feet and 6 inches	19	1.8	25	4.0	56	32.5	100	3.9
12	Endurance	Chinning the bar (pull ups) 10 times	173	11.6	200	32.1	743	78.8	1,116	43.3
13	Power	Standing broad jump 7 feet on mat	18	1.7	37	5.9	332	34.2	387	14.9
14	Endurance	Mile run - minutes minimum	172	16.2	178	28.6	717	76.1	1,067	40.9
Total			1,063	40.4	623	23.7	943	35.8	2,629	100.0

(Physical Education Classes for Men University of Illinois September 1942 2,629 Cases)

standards in fundamental events which physical educators claim to be significant in motor fitness.

The results also show that every item in the motor screen test has some discriminating value in that there are the fewest failures in the satisfactory group more in the restricted group and most of all in the basic group. It is not easy to arrange a satisfactory test with only a few items because there are various aspects to motor fitness which are highly specific in themselves and deserve separate emphasis. The same items used to discriminate the basic group from the restricted group are not equally good for discriminating the satisfactory group from the restricted group. For instance the differential in percentage failures between the basic and restricted groups is greater for skin the cat mile run and chinning. Then follow the dive and roll extension press up squat stand medicine ball put bar vault, standing broad jump leg lifts and sit ups trunk flexion man lift and let down foot and toe balance and trunk extension. For separating the satisfactory group from the restricted group the items rank as follows for differentiating value: leg lifts and sit ups chinning, running dive and roll are best. Then in order are mile run extension press up skin the cat squat stand trunk flexion medicine ball put trunk extension standing broad jump bar vault, foot and toe balance and man lift and let down. Obviously an item is not any good

but not as much as 100 yards were an additional 40.13 per cent or a total of 66.68 per cent who could not meet the 100 yard swimming standard. Some 20.92 per cent stated that they could swim as much as 440 yards, and 12.40 per cent stated that they were life savers.

TABLE 4—Classification of Basic Group

	Number	Per Cent
NS Unable to swim 75 feet after jumping into deep water feet first (non-swimmers)	235	37.84
PS Unable to swim 100 yards any way at all (poor swimmers)	133	21.42
AS Able to swim 100 yards but unable to demonstrate crawl back crawl breast and side stroke 75 feet each (average swimmers)	159	25.00
SS Able to swim 440 yards and demonstrate four strokes as named (superior swimmers)	73	11.76
LS Qualified in life saving with one or more of the national life saving organization (life savers)	21	3.35
	611	100.00

It was decided to investigate this situation further by requiring the men in the basic group to take the swimming test in the pool. Exactly 621 men reported at the pool for the test and were classified as shown in table 4.

By actual test 59.26 per cent, or 368 men out of 621, could not pass the 100 yard test in the pool. By test 84.86 per cent could not swim 440 yards, and 80.6 per cent said that they could not on the questionnaire.

RESULTS IN PHYSIQUE RATINGS

With the understanding that men with physique ratings below 4 would be classified in the basic group and assigned to developmental work, 321 men failed to pass the standard because of having very poor posture, soft muscles under contraction or more than an inch of fat in double fold over the abdomen. The average rating for the entire sample was 5.45, for the satisfactory group it was 6.20, for the restricted group 5.57 and for the basic group 4.48. Not all men in the basic group had low ratings on physique. The correlation between the physique ratings and the motor fitness screen test scores for 680 cases was computed to be 0.318.

A careful study and classification of two samples of Illinois men show that according to Sheldon's body type criteria 66 out of 168 men were rated above average in physique and were in the lower 20 per cent in motor fitness by the screen test scores.

RESULTS IN ORGANIC FITNESS

Using the Schneider test as a measure of organic condition, 507 men in the basic group were tested. The reliability of the testing was 0.860. The mean score was 10.805 with the standard deviation 4.368. There were 128 men with scores below 9 classified as organically unfit (untrained).

IMPLICATIONS OF MOTOR UNFITNESS

Several important implications of the results may be pointed out:

- 1 The deficiency of large numbers of young men in fundamental motor ability traits of balance, flexibility, agility, strength, power and endurance is a fact. The proportions of motor unfitness are appalling.

- 2 Physical training programs are not compensating rapidly enough for urbanization with its associated mechanization, indoor work, dependence on motor vehicles and lack of the necessity of hard physical work in youth.

- 3 Large numbers of young men are entering adult life unconditioned and unmotivated to maintain physical fitness. This trend may contribute greatly to high accident rates, rapid loss of health after the age of 30 and widespread chronic disease because of the lack of preventive hygiene and conditioning work for the body.

- 4 Physical education and recreational programs have been inadequate, possibly because of inadequate time, facilities and leadership. In addition, the programs too infrequently focus on the physical fitness objective in terms of big muscle and organic endurance criteria. The socialization of the programs has possibly hurt the conditioning value of the activities. Many activities, such as bowling, dancing, socialized games, archery, bait and fly casting, badminton and tennis possibly contribute very little as they are taught in typical physical education or recreation classes.

- 5 Basic motor fitness training would include deliberate emphasis on ability in a wide range of activities for balance, flexibility, agility, strength, power and endurance, apart from health knowledge, rules of the game, social play relations or form in refined physical skills.

- 6 The fact that 60 per cent of those failing to pass the motor fitness test cannot swim 100 yards, and 85 per cent of these cannot swim 440 yards, is a deplorable fact which indicates lack of organization in the schools to teach the important skills of swimming. Thousands of drownings in the war are directly attributable to this omission.

- 7 Physique is an important base for evaluating physical fitness and it correlates 0.318 with the motor fitness screen test scores, but this evidence suggests that motor fitness is quite unique apart from physical proportions and is due to training of the gross neuromuscular abilities for balance, flexibility, agility, strength, power and endurance. Likewise, organic efficiency is an important base, but the Schneider test correlates only 0.381 with the motor fitness screen test scores, although it correlates as high as 0.85 with endurance running criteria. This would seem to indicate that for a rounded emphasis physique, organic efficiency and motor efficiency need to be stressed, not one to the exclusion of the others.

- 8 These facts imply the great importance of physical fitness work from the dynamic approach as used in physical education. The findings suggest a fruitful area of work of primary importance from the health and safety point of view.

PHYSIOPATHOLOGIC ASPECT OF THE DISORDERS OF MUSCLES IN INFANTILE PARALYSIS

PRELIMINARY REPORT

JOSEPH MOLDAVER, M.D.

NEW YORK

Infantile paralysis is not merely an acute disease of the anterior horn area of the gray matter of the spinal cord. Lesions are also found in the posterior horns in the sympathetic column and in the dorsal root ganglions. The white matter and the vessels of the pia are also involved. In addition, any part of the central nervous system, cerebral cortex, cerebellum, pons and medulla may be affected. However, the affinity of the virus for the gray matter of the cord is striking. After the period of acute inflammation, resolution takes place. It is usually complete in the white matter and sometimes even in the gray matter. In many cases anterior horn cells are destroyed or damaged by direct action of the virus. Distribution and intensity of the lesions vary widely.

These lesions explain the symptomatology of infantile paralysis very well. After a stage of general malaise, as seen in any infectious disease, there are signs of meningeal irritation, pain, followed more or less quickly by paresis or paralysis. The irritation of the meninges, dorsal root ganglions, posterior roots and posterior horns explain the pain which is one of the definite symptoms of the disease. The lesions of the anterior horn cells explain the motor deficiency, ranging from pronounced paralysis to slight weakness.

The paralysis is a flaccid one. The muscles become atrophic and toneless, the tendon reflexes being absent.

This study was sponsored by the National Foundation for Infantile Paralysis.

From the Department of Neurology, Columbia University College of Physicians and Surgeons and the Neurological Institute of New York.

The author is indebted to Dr. Tracy J. Putnam for his help and interest in this work. Dr. Paul F. A. Hoefer helped in preparing the manuscript and extended the use of the electromyographic equipment. Drs. Alan deF. Smith and William R. Snow referred some of the patients.

as well as some cutaneous reflexes. Tenderness on pressure of the muscles and pain caused by active and passive motion are also common findings. Hyperesthesia is found in most of the cases. In the weak or paralyzed muscles the existence of neuromuscular degeneration can easily be demonstrated and is the consequence of the lower motor neuron lesion.

Recently a new concept of infantile paralysis has been described by Kenny¹ and has been approved by some physicians. This new concept is fundamentally different from the one accepted for more than a century. The phenomena described in this concept are (1) muscle 'spasm,' (2) 'mental alienation' and (3) 'incoordination.' Only recently the existence of some true paralysis has been accepted by the proponents of this concept. Muscle spasm is regarded as the most damaging symptom in poliomyelitis and is said to lead to degeneration if not treated. The muscles opposed to those in 'spasm' become 'alienated,' divorced or erased from the patient's mind. The muscles which are in "spasm" are the damaged ones. 'Spasm' is described as being generally present in the following groups: neck, back, hamstrings, calf and pectoralis muscles. The "alienated" muscles are nonfunctioning not because they are paralyzed by the lesions of the anterior horn cells but rather because for some unknown reason they are unable to receive impulses. The dissociation of the muscle from the brain is regarded as due to some physiologic block. "Alienated" muscles may become permanently nonfunctioning if not treated. In summary according to this concept, infantile paralysis is a "spastic" not a flaccid paralysis, the muscles affected by this disease are those in "spasm." The antagonist muscles are "mentally alienated," and some muscles show incoordination. The danger of paralysis lies mainly in allowing "spasms" to continue.

In view of this concept investigations were conducted in order to find whether or not these newly described symptoms actually exist and if they were actually overlooked for more than a century.

EXPERIMENTAL RESULTS

Forty-nine patients were tested. Neuromuscular degeneration was explored by chronaxia measurements and "spasm" was studied in some of these patients mostly by electromyograms. Muscles which might be considered to be "alienated" as well as muscles in "spasm" were primarily explored by chronaxia measurements. Muscles regarded as normal clinically were also studied.

The degree of neuromuscular degeneration can be evaluated by chronaxia measurements. This test allows us to detect slight neuromuscular degeneration. In all 'alienated' muscles there was evidence of neuromuscular degeneration. In most of the "alienated" muscles, the nerves and muscles were in a state of partial neuromuscular degeneration. In a partial neuromuscular degeneration some of the muscle and nerve fibers are damaged while other fibers of the same muscle escape degeneration. This part of the muscle is therefore still able to respond to stimulation of its motor nerve. The extent of the lesion in each individual muscle depends obviously on the number of anterior horn cells damaged. Some of the muscles considered to be 'alienated'

according to the definition of Kenny¹ were found in total neuromuscular degeneration. This means that all the fibers composing the muscle were in deep degeneration with pronounced increase in the chronaxia, and the muscle was no longer able to respond to stimulation of its nerve. Thus in these patients different degrees of injury of lower motor neuron lesions were found.

Paralysis and neuromuscular degeneration are generally found in certain muscles or groups of muscles. These muscles are in order of frequency in the upper extremity the deltoid, biceps, brachialis anticus, brachioradialis, pronator teres, opponens pollicis, infra- and supraspinatus and clavicular part of pectoralis major, in the trunk the rectus and oblique abdominis muscles, mostly in their lower part, in the lower extremity the tibialis anticus, quadriceps, extensor digitorum brevis, extensor proprius hallucis, extensor digitorum longus and peronei. The hamstring and the calf muscles were also affected but less frequently.

According to the definition of Kenny the word "spasm" is used to express a certain degree of reflex shortening of the muscle. It can sometimes be located by observation or gentle palpation of the muscle, but it is usually demonstrated when the muscle is passively stretched. Examination of the patients who were the subjects of this report showed that "spasm" can be easily confused with a pseudospasm.

In some cases pain was caused by passive stretching of the muscles without resulting contraction, while in other cases there was definite contraction in response to stretch without severe pain. Some patients may show contracture or shortening due to replacement of some muscle fibers by fibrous tissue. The latter can be confused with "spasm" if pain is elicited by pulling of the muscle. The only means of detecting "spasm" with accuracy is by the study of action potentials.

Where "spasm" was present, electrical activity was recorded by stretching of the muscles. This test sometimes appeared to be difficult, because the interference of voluntary movement has to be carefully avoided. When the muscle is stretched and pain elicited, the patient sometimes tends to resist. With most patients complete relaxation could be induced and interference of voluntary motion could be avoided.

Muscles in definite "spasm" showed generally normal chronaxia, that is to say no trace of neuromuscular degeneration could be evidenced. On the other hand, in muscles with total neuromuscular degeneration there was no "spasm" at any time. Some patients were found to have partial neuromuscular degeneration also in the hamstring and calf muscles simultaneously with some "spasm." In such muscles the fibers which escape degeneration have normal chronaxia and are those in "spasm."

Action potentials of sixteen patients were recorded. Whether or not the legs were involved "spasm" was recorded in the hamstring muscles of all these patients. This phenomenon in the hamstring muscles was also pronounced in a patient who had only meningeal signs. "Spasm" was recorded in the gastrocnemius muscles of some patients but very rarely in the extensor digitorum longus, tibialis anticus and quadriceps. In the abduction of the thigh and in the tensor fasciae lata "spasm" could not be recorded. In the upper extremity activity produced by stretching of the muscles was found less frequently. It was sometimes found in the biceps, in the extensor digitorum communis very seldom in the flexor digitorum sublimis and in none

¹ Kenny, Elizabeth. *The Treatment of Infantile Paralysis in the Acute Stage*. Milwaukee and New York: Bruce Publishing Company, 1941. Lohr, John F. in collaboration with Sister Elizabeth Kenny. *The Kenny Concept of Infantile Paralysis and Its Treatment*. Bruce Publishing Company, 1943.

of the cases in the pectoralis. As a rule "spasm" could not be detected at rest in any of these patients except one. Thus it was found that the more advanced the degeneration, the less extensive was the "spasm."

COMMENT

The principal and the most crippling symptoms of the disease are muscle paralysis and paresis. Some muscles are painful and tender. In some muscles the so-called "spasm" is evidenced. The paralysis is always flaccid and associated with neuromuscular degeneration, the latter can easily be detected by chronaxia measurements.

As stated previously, the permanently paralyzed and degenerated muscles are exactly the opposite of those considered to be in "spasm." The principal location of muscle "spasm" and the most frequent distribution of neuromuscular degeneration show obviously that "spasm" does not lead to neuromuscular degeneration. "Spasm" is consequently not the "most damaging symptom" of the disease.

We know that lower motor neuron lesions lead to flaccidity, atonia and abolition of the tendon reflexes, and this is the contrary to "spasm" or hypertonicity. It has been shown² that muscles in degeneration are frequently in fibrillation, but activities of single fibers cannot give a sustained contraction or tetanus of a muscle and thus cannot be responsible for "spasm."

In a partial degeneration, part of the muscles and nerve fibers escaping degeneration respond like normal structures. It is not surprising, therefore, that in patients with unilateral partial degeneration of the hamstring and calf muscles, "spasm" might be found on both sides, though always more pronounced in the normal leg.

It is worth while to notice that at the onset of the disease the principal location of the so-called "spasm" is, roughly speaking almost the same as that found in any meningitis or meningeal irritation in the neck, back, hamstring, and posterior calf muscles. In infantile paralysis some other muscles may be found in "spasm." In meningitis one generally does not find for instance, tension in the pectoralis major or the latissimus dorsi. It should also be mentioned that in some severe lower motor neuron injuries of different etiology than poliomyelitis there may be definite shortening of the uninvolved antagonist muscles. For instance, in a lesion of the brachial plexus with paralysis of the deltoid, biceps, brachioradialis, coracobrachial, triceps, extensor of the fingers, it is not infrequent to find definite shortening which might be called "spasm" in the normal superior trapezius, pectoral and latissimus dorsi. The same distribution is frequently found in poliomyelitis. Thus in a peripheral lesion of the lower motor neuron, and without any lesion of the spinal cord, one might have a similar picture of "spasm." It is a well known fact that, if a protagonist muscle is paralyzed, the stretch reflex of the antagonist muscle is always increased. There are, therefore, obviously at least two mechanisms of "spasm" one being the meningeal irritation of the posterior roots and the second being an increase of the activity of the opposite muscles to those paralyzed by a lower motor neuron lesion.

There is a third factor which may also account for part of the mechanism of "spasm", inflammation of the posterior ganglions and posterior horns where part of the posterior roots end. Lesions of the sensory protoneuron explains that occurrence of severe and continuous pain. It also explains the hyperesthesia and some other sensory disturbances found in this disease. This also allows us to understand why pulling of some muscles may elicit pain without giving rise to any tension or "spasm." If the anterior horn cells are destroyed, they are not able to respond to the stimulation of the sensory end organs. "Spasm," as it is said, can most easily be demonstrated by stretching of the muscles. In doing so, centripetal impulses mostly from the muscle spindles and also from other sensory organs of the tendons are sent to the spinal cord and referred as pain.

Thus the mechanism of the so-called "spasm" is threefold: meningeal irritation of the posterior roots, involvement of the sensitive protoneuron and an exaggeration of the tonus in the muscles opposed to those paralyzed or weak. In the latter phenomenon it is known that there are not only mechanical factors but also absence of the normal inhibitory influence (Sherrington's reciprocal innervation) of the involved muscles on their antagonists. "Spasm" has not therefore a unique or single cause. Under the heading of "spasm" there may be even three different phenomena. One of the three factors is sufficient to elicit a reflex response and a shortening of the muscle. The meningeal component of "spasm" disappears relatively quickly. This meningeal reaction explains why it is more pronounced at the onset of the disease. Irritation of the posterior horns and ganglions may last longer than meningeal reaction. The last and the most persistent type of "spasm" is the one due to the increase of the normal tonus in strong muscles.

Besides these three factors, it should be mentioned that in a normal subject the stretch reflex of the hamstring and calf muscle was sometimes as manifest as in any case of poliomyelitis. In normal subjects definite action potentials were recorded. The pulling of these muscles did not elicit pain, but the tension was uncomfortable.

According to Kenny's concept, "alienated" muscles are muscles which have lost their ability to produce voluntary movement, these muscles are divorced from the mind because their antagonists are in "spasm." The findings reported here show definitely that no mental condition or any "physiologic block" is needed to explain "alienated" muscles. No one has been able to demonstrate that paralysis ever occurs in poliomyelitis without a certain degree of neuromuscular degeneration. This is the result of the damage of the anterior horn cells. Depending on the intensity and the extent of the lesions, the degeneration will be more or less well defined. This will be indicated by chronaxia measurement. It explains why some so-called "alienated" muscles may recover quickly. The reason for this is that we are dealing with a slight degree of partial degeneration.

Some muscles considered to be "alienated" were found in total neuromuscular degeneration, thus indicating that all the fibers composing the muscle were in deep degeneration. The chronaxia was much increased. These muscles are no longer able to respond to stimulation of its nerve. In infantile paralysis muscles with pronounced degeneration are doomed because their loss of function is the result of destruction of

all anterior horn cells. A muscle is generally supplied by motor neurons from several segments of the spinal cord. Therefore total degeneration implying a more widespread lesion, is not as frequent as partial degeneration. Other muscles also considered to be "alienated" had completely disappeared and were replaced by fibrous tissue. In these muscles the proliferation of fat and connective tissue had masked the atrophy.

It was not infrequent to find a deep neuromuscular degeneration in the pectoralis major, the clavicular part, while the sternal part was normal and in 'spasm'. In this instance the degeneration was as pronounced in the clavicular part of the pectoralis major as it was in the corresponding deltoid. The reason for this is obvious: we were dealing with a deep injury in the fifth and sixth segments of the spinal cord while the lower segments were spared.

The third and least important symptom described by Kenny is 'incoordination'.

Muscles partially involved are obviously weak and the force employed is not well adapted to the aim of the movement. If, among the muscles which have to carry out motion one or several are paralyzed or paretic there will necessarily be considerable disturbance in the function of the extremity. The automatic regulation of the movement will be interfered with as well as the voluntary movement. This, of course, might be called "incoordination." We should, however, know that the mechanism of this symptom is to be found in the maldistribution of the impulses reaching muscles with different ability to respond, this ability to respond being the result of damage to some motor units.

SUMMARY

A new concept of infantile paralysis was recently described by Kenny and has been approved by some physicians.

According to this concept three principal symptoms are found: "spasm," "mental alienation" and "incoordination."

In view of this new concept, investigations were conducted. Forty-nine patients with infantile paralysis were tested with chronaxia measurements and in some cases action potentials were recorded. The following conclusions were drawn:

1 "Muscle spasm" is not "the most damaging symptom" and does not lead to neuromuscular degeneration. "Spasm" is not an entity but a complex phenomenon. It is the result of a combination of the normal stretch reflex, meningeal irritation of the posterior roots, increase of the normal tonus in healthy and strong muscles or muscular fibers opposed to weak or paralyzed muscles, lesions of dorsal root ganglions and posterior horns. Pain is a common symptom in acute poliomyelitis. This is a referred pain which is increased by stretching of the muscles.

2 In "alienated muscles" there is neither a functional paralysis nor a "physiologic block." That these muscles have partially or completely lost their power to contract is due to the fact that the anterior horn cells are damaged or destroyed. In the paralytic or paretic muscles considered to be "alienated" there is always some degree of neuromuscular degeneration.

3 "Incoordination" does not consist in a misdirection of nerve impulses. It is caused, if at all, by the inability of partially or totally denervated muscles to respond to otherwise normal nerve impulses.

COLD HEMAGGLUTININS IN ACUTE HEMOLYTIC REACTIONS

IN ASSOCIATION WITH SULFONAMIDE MEDICATION AND INFECTION

WILLIAM DAMESHEK, MD

BOSTON

Although mild anemia following the use of the sulfonamide compounds is common the appearance of a severe and fulminating hemolytic anemia is unusual. Because this type of reaction, when it occurs is unexpected and usually out of proportion to the amount of drug that has been administered it has been thought to be an example of hypersensitivity or idiosyncrasy. However definite proof of this or other type of pathogenic mechanism has not been discovered. In the cases reported here in which acute hemolytic anemia developed during the course of an acute infectious disease and following administration of sulfathiazole and sulfadiazine, a potent hemagglutinin was found. This agglutinin which was most active at ice box and room temperatures ("cold" hemagglutinin), reacted with the red cells of large numbers of prospective group O donors and with those of the patient (autoagglutinin). Although temperatures of 37 and 56 C caused inactivation, the agglutinin was reactivated at room or ice box temperatures. The possibility is present that the agglutinins in these cases were a factor in intravascular hemagglutination and hemolysis with the appearance clinically of acute hemolytic anemia and hemoglobinuria. The relationship of abnormal hemagglutinins to severe hemolytic reactions is discussed, together with the importance of the recognition of cold hemagglutinins in performing compatibility tests for transfusion purposes. The presence of cold hemagglutinins in atypical pneumonia has recently become diagnostically significant. These abnormal antibodies may also be important in the development of acute hemolytic anemia in this and other diseases.

REPORT OF CASES

CASE 1—F B, aged 26 a sales engineer became ill with mild fever, sore throat and cough. Although signs of pulmonary consolidation were not evident the patient was given sulfathiazole in the dosage of 1 Gm every four hours for two days following which sulfadiazine in the same dosage was administered. In all, he took approximately 9 Gm of sulfathiazole and 4 Gm of sulfadiazine. Another physician (Dr Edward Broderick) was called on the fourth day and the sulfadiazine was discontinued. Symptomatic treatment for the cough being given. Since there was continued mild fever of 99 to 101 F agglutination tests for typhoid, paratyphoid and undulant fever were done and reported negative. The sputum was negative for acid fast bacilli and pneumococci and a throat culture revealed no pathogenic organisms. On August 28 one week after sulfadiazine had been discontinued the patient complained of passing dark urine. On examination he was found to be somewhat pale and sallow, the red blood cell count was 3.7 million per cubic millimeter. On August 29 the patient was pale, dyspneic and uncomfortable, his urine was a dark wine color. He was then admitted to the Leonard Morse Hospital of Natick, Mass. with the presumptive diagnosis of sulfathiazole poisoning. The lungs showed fairly numerous scattered crepitant rales but no definite evidence of consolidation. The urine was dark burgundy red with a heavy trace of 'albumin', a rare red cell in the sediment but no casts. The

From the Joseph H. Pratt Diagnostic Hospital and the Biol. Laboratories of the Boston Dispensary.

blood sulfathiazole level was zero. Blood examination revealed hemoglobin 60 per cent (Sahli), red blood cells 330 million, white blood cells 29,400, polymorphonuclears 84 per cent with an occasional myelocyte. Since a transfusion seemed desirable, the patient's blood was typed and found to be in group O (international). Numerous prospective group O donors were then cross matched with the patient's serum by the slide method at room temperature but were found to be "incompatible"—i.e. there was decided agglutination. Transfusion was accordingly postponed.

On August 30 the patient's condition was much worse. Pallor had noticeably increased and there was moderate jaundice. He was very dyspneic and was passing small amounts of red-brown urine which gave a strongly positive benzidine reaction. The red blood cell count was now 226 million and the white blood cell count 42,200. A consulting internist made the diagnosis of 'hemolytic streptococcus infection, chiefly in the throat and lungs, with question of blood stream invasion' and advised the readministration of sulfadiazine in a dosage of 1 Gm every two hours for two doses, then every hour. On this regimen the patient's condition became rapidly worse. An x-ray film of the chest showed "rather extensive mottled dullness in the right lung fields extending from the hilus to the right base, suggesting a virus pneumonia."

On August 31 the patient's condition was critical. He was stuporous, extremely pale and moderately jaundiced. The red blood cell count was under 20 million and the leukocyte count was 43,000. The red cells showed distinctive spherocytosis and polychromatophilia, the many polychromatophilic macrocytes contrasting sharply with the small, dense appearing spherocytes. An occasional nucleated red cell was seen. Differential count of the white cells showed a severe polymorphonuclear leukocytosis with immature polymorphonuclears, including an occasional myelocyte. Four nucleated red cells were seen in counting 100 white cells. The platelets were abundant. The hypotonic fragility test was 0.56 to 0.24 per cent. The blood bilirubin was 3.6 mg per hundred cubic centimeters.

The diagnosis of acute hemolytic anemia with hemoglobinuria secondary to administration of a sulfonamide compound was made and sulfadiazine was immediately discontinued. It was suspected that the "incompatibility" reactions against group O cells were due to the presence of a cold hemagglutinin. Examination of the patient's serum revealed a potent hemagglutinin which had the following characteristics: greatest activity at ice box (4 C) and room (20 C) temperatures, agglutination titer 1:128,¹ inactivation at blood temperature (37 C) and at 56 C, reactivation when the temperature was lowered to 20 C, agglutinating activity against red cells of all group O individuals tested, autoagglutination, slight agglutination of guinea pig and rabbit red blood cells, hemolysis in low titer of rabbit red blood cells in the presence of guinea pig complement, no isohemolysis or autohemolysis demonstrable. By use of the Landsteiner test tube technique at 37 C,² compatible group O donors were obtained and the patient was given a transfusion of 500 cc of blood. The precaution was taken of keeping the blood continuously warm throughout its removal from the donor and administration to the patient. By means of a U tube connection, 350 cc of a 5 per cent solution of sodium bicarbonate was continuously given during the transfusion. The patient's condition was almost immediately improved and on the following morning the urine had lost its brownish red color. He was given another transfusion of properly matched and warmed blood on this day (September 1), followed by an infusion of 500 cc of 5 per cent solution of sodium carbonate.

On September 2 the patient's condition was greatly improved. There was still a slight elevation in temperature. Jaundice was no longer present. The urine was completely normal in color and free from albumin,³ and the benzidine reaction was negative. The red blood cell count was 279 million and the leukocyte count had dropped to 27,000. On September 3 the patient's temperature was normal. On the fourth day the red

blood cell count rose to 334 million and the leukocyte count was 17,500. Although leukocytosis (17,000 to 20,000) persisted for another week, the course was now one of continuous improvement. On September 12, when the patient was discharged from the hospital, the red cell count was 392 million. On September 19 it was 45 million. Tests of the patient's serum on October 2 indicated almost complete disappearance of the cold hemagglutinin, which was now active only at ice box temperature in a titer of 1:2.

CASE 2—L. M., a housewife aged 50, had an acute illness with fever on Dec 15, 1942. Three days later she was seen by a physician, who prescribed sulfadiazine. This was apparently taken for three days, the total dosage being between 6 and 12 Gm (the stories varied). The therapeutic response to the drug being unsatisfactory, diagnosis of a virus infection was made. She began to feel very weak several days later. On December 31, when seen by Dr. Small of Norwood, Mass., she presented evidences of bilateral patchy pulmonary consolidation suggesting a "virus" pneumonia. There was a lemon yellow tint to the skin, and since the dyspnea seemed out of proportion to the degree of pulmonary involvement the patient was admitted to the Norwood Hospital on Jan 1, 1943. She was in a desperate condition, with extreme pallor and moderate icterus. The temperature was 103 F. The blood showed a hemoglobin content of 28 per cent, a red cell count of 700,000 per cubic millimeter and a leukocyte count of 23,000 with 80 per cent polymorphonuclears. Great difficulty was experienced in performing red cell counts or making blood smears because of the strong tendency of the red cells to clump within the pipets and on the hemacytometer, the blood smears showed masses of agglutinated red cells. These phenomena were later obviated by warming the Hayem solution, the pipets, the hemacytometer and slides immediately before use. The patient's blood group was O (international), but cross matching with the patient's serum against numerous prospective group O donors showed "incompatibility" in all. In addition there was autoagglutination. The possibility of a cold hemagglutinin was suspected by the pathologist, Dr. Schultz, and compatible donors were obtained by performing the cross matching test at incubator temperature. Four transfusions of 500 cc of citrated blood were then given, great care being taken to keep the blood and all utensils warm during the procedure. After the second transfusion, on January 3, the red blood cell count rose to 267 million, but on January 4 it was 220 million and on January 5 it was 205 million. On January 6 when I saw the patient, there was only slight pallor and icterus. The lungs showed no consolidation. The liver was readily felt two to three finger-breadths below the right costal margin but the spleen was not felt. The hemoglobin content was 54 per cent and the red cell count 271 million. The blood serum at this time showed no abnormal agglutinins. Without further therapy the patient made an uneventful recovery.

CASE 3—G. W., aged 24, an upholsterer, was admitted to the J. H. Pratt Diagnostic Hospital on Feb 14, 1943. About fifteen days before admission, an acute illness developed with fever, malaise, severe headache and aching pains in the shoulders, arms, back and legs. During the first week of his illness sulfadiazine in a total dosage of approximately 6 Gm was administered. This was apparently without effect, since a temperature of 101 to 103 F continued and a severely sore throat developed on the seventh day of illness. He then noticed enlarged glands in the neck and later in the groins. His urine became very dark. On February 10 he became quite weak. His physician, Dr. Leavitt of Stoneham, Mass., noted jaundice and a rash on the trunk. On admission to the hospital he looked weak, pale, thin and jaundiced. An eruption composed of fine macules which faded on pressure was present over the skin of the abdomen. A small shallow ulceration of the buccal surface of the lower lip and a large, somewhat deeper one on the right tonsillar fossa were present. The gingivae were normal, no petechiae were present. Examination of the heart and lungs was negative. The spleen was readily palpable three finger-breadths below the left costal margin but the liver could not be felt. There was generalized lymphadenopathy with hazelnut sized glands being readily felt in the cervical, axillary, inguinal and femoral nodes.

1 Serum dilution, total solution 1:512.
2 Dameshek, William, and Schwartz, S. O. The Presence of Hemolysis in Acute Hemolytic Anemia. *New England J. Med.* 215: 75 (Jan 13) 1938.
3 The "albumin" in cases of hemoglobinuria is probably due to hemoglobin present.

The clinical diagnosis was infectious mononucleosis with jaundice. The urine was milky colored and contained 2 plus bilirubin (bile) and increased quantities of urobilinogen (4 plus) and urobilin (3 plus). By the Wallace Diamond technique the urinary urobilinogen was positive in a dilution of 1:160. There was no hemoglobinuria as determined by the benzidine test. The total blood serum bilirubin (Malloy-Evelyn technique) was 6 mg per hundred cubic centimeters with 3.4 mg 'direct' and 2.6 mg of the indirect variety. The blood showed hemoglobin 63 per cent 9.8 Gm (Evelyn photoelectric) red blood cells 3.10 million white blood cells 12,500 platelets 285,000, reticulocytes 5.6 per cent. The lymphocytes were of all shapes, sizes and staining characteristics with a number of large, early cells characteristic of those seen in infectious mononucleosis. The red cells showed definite spherocytosis, which contrasted strikingly with the large polychromatophilic cells present. The hypotonic fragility showed beginning hemolysis at 0.72 per cent sodium chloride and complete hemolysis at 0.24 per cent.

The clinical diagnosis of infectious mononucleosis was thus substantiated by the typical findings in the blood smear, but the presence of anemia, spherocytosis, increased hypotonic fragility, slight reticulocytosis and greatly increased urinary urobilinogen indicated a hemolytic process. The possibility that this might be due to the recent sulfadiazine administration was suspected, and because of our experience with abnormal agglutinins in the previous cases the serum was investigated. A potent abnormal hemagglutinin was found with the following characteristics: agglutination of the red cells of all the blood groups including those of group O; autoagglutination, most pronounced agglutination at ice box and room temperatures, inactivation at 56 C; slight but no definite inactivation at 37 C; no isohemolysins or autohemolysins; slight hemolysis of guinea pig and rabbit cells with inactivation at 56 C. A very strong sheep cell agglutinin (in serum inactivated at 56 C) was also found; this was positive in a total serum dilution of 1:1,024. This heterophile agglutinin was thus entirely distinct from the isoagglutinin which was active in temperatures below 56 C. Another unusual finding was present. Venous blood when removed allowed to clot and to stand at ice box or room temperature developed a reddish tinge, then a striking degree of hemoglobinemia in the serum. After twenty-four hours of standing the blood serum contained approximately 150 mg of hemoglobin per hundred cubic centimeters. When serum was immediately removed from the clot and inactivated by heat and then returned to the clot, further hemolysis did not occur. Hemolysis did not occur in blood which was ovalated and allowed to stand at room or ice box temperature for the same length of time as the clotted blood. There was, however, a small zone of hemolysis just above the layer of sedimented red blood cells. When red cells which had been washed several times (three to seven) in isotonic solution of sodium chloride were allowed to stand at ice box temperature they caused hemoglobin discoloration of the saline solution. This gradually diminished as the patient improved, as did the phenomena of isoagglutination, autoagglutination and stasis hemolysis. By the time of the patient's discharge on February 20 they had completely disappeared. The heterophile agglutination test on this date was still strongly positive; however, to a total dilution of 1:512.

At first typing of the red cells for the blood group was impossible since, even with washing the red cells three to seven times an AB blood group was obtained. After four days, however, the autoagglutinin adsorbed to the red cells had so diminished that correct blood typing was possible when it was found to be group O.

There was a spontaneous rise in the reticulocytes to 13 per cent on February 20 followed by a gradual rise in the red blood cell count. Simultaneously the patient made a slow but steady clinical improvement with gradual regression in fever, jaundice, lymphadenopathy and splenomegaly. The temperature reached normal on February 20. On March 5 there was only slight lymphadenopathy and the spleen was barely palpable. On this date the red cell count had risen to 5.2 million, the leukocyte count was 6,200 per cubic millimeter and the lymphocyte percentage had fallen to 52. The heterophile agglutination test was now positive in a dilution of 1:128, no abnormal agglutinations were present.

COMMENT

Acute hemolytic anemia which results during the administration of the sulfonamide compounds differs strikingly from the mild hemolytic anemia which develops so commonly, particularly after administration of sulfanilamide. It is rapid in its onset and progress its effects are often violent and it may even be fatal. Since only an occasional patient develops the acute condition it has been thought to be the result of an idiosyncrasy or allergy, although actually the mechanisms involved are quite obscure. Long, Bliss and Feinstein⁴ readministered small doses of sulfanilamide to 4 persons who had previously had acute hemolytic anemia following administration of the drug. In 3 instances anemia developed after a few days—on the identical day which had previously witnessed the appearance of the anemia. The presence of autoagglutinins in the cases of Antopol and his associates⁵ and of Rothstein and Cohn⁶ and of cold isohemagglutinins and autohemagglutinins in the present cases suggests a possible relationship between these substances and the development of the anemia. In several previous papers Schwartz and I⁷ have pointed out the importance of the presence of hemolysins in acute hemolytic anemia. Agglutinins and hemolysins are both antibodies which are often closely related. Some substances that are agglutinins under one set of conditions are hemolysins under another. Miller and I⁸ have investigated this possibility further and have demonstrated that agglutinins injure the red cell membrane, making it susceptible to hemolysis by trauma and stasis. Ham and Castle⁹ have stressed erythrocytostasis—due perhaps to agglutination of red cells—as the sole cause of hemolysis.

Since the time of Vidal,¹⁰ agglutinins have been found in many cases of acute acquired hemolytic anemia. It is possible that autoimmunization occasionally develops with the production of an antibody active against the patient's own red cells. A somewhat similar condition appears to hold true in erythroblastosis fetalis¹¹ in which an anti-Rh agglutinin develops in the mother by isoimmunization with the fetus's red cells, which except for the presence of the Rh agglutinin are identical with those of the mother.

The possibility is present that a sufficient number of red cells of a patient taking a sulfonamide compound may be so altered as to serve as an antigen with the subsequent formation of an agglutinating antibody. Another, perhaps more likely, possibility is that certain infections may themselves result in the development of abnormal hemagglutinins. This we have previously commented on in our review "Acute Hemolytic Anemia"¹² and in a personally observed case of acute hemolytic anemia occurring with type XVII pneumo-

coccus pneumonia¹² Peterson, Ham and Finland¹³ have recently reported "that the great majority of the patients with primary atypical pneumonia tested this season showed cold agglutinins in dilutions of serum or plasma ranging from 1:10 to over 1:10,000 at 0 C." It is possible that the combination of a high titer of abnormal autohemagglutinins and of a sulfonamide compound might result in agglutination and injury of red cells within the patient's own circulation and thus in the development of hemoglobinuria and acute hemolytic anemia. Since the hemagglutinins are generally more active at temperatures lower than 37 C, it is possible that they have their greatest effect either in peripheral vascular areas or in those organs, such as the spleen, which have a relatively static circulation. The development of *in vitro* hemolysis in case 3 when the clot was allowed to remain in the serum is perhaps evidence in favor of this assumption. It may be of considerable practical importance to take measures to prevent chilling of the patient with "virus" pneumonia and other conditions in which a cold hemagglutinin is found.

Similar mechanisms may be present in other hemolytic conditions, as in the "blackwater fever" of malaria¹⁴. The presence of an abnormal isohemagglutinin and autohemagglutinin in our case of infectious mononucleosis is of unusual interest. In this disease, for some reason thus far obscure, heterophilic agglutinins active chiefly against sheep red cells are present and have assumed great diagnostic importance. Isoagglutinins have thus far not been described. Since an abnormal isohemagglutinin was present in this case in association with acute hemolytic anemia and the use of a sulfonamide compound, it is reasonable to suspect a relationship between them.

The importance of the recognition of abnormal agglutinins cannot be overestimated. Since most testing for transfusion purposes is still performed by the slide technic at room temperature, the serum of the recipient with the cold agglutinin will routinely agglutinate the red cells of all persons tested, group O or otherwise. As in the present case, these individuals are normally classed as "incompatible" and a transfusion will often be postponed until the patient's condition is critical. Use of the Landsteiner-Levine test tube technic at both ice box (or room) and incubator temperatures is essential, not only because it demonstrates the "cold" nature of the agglutinin but because it is more sensitive than the slide method and will thus occasionally demonstrate a "warm" hemagglutinin or hemolysin which has previously been unrecognized. The agglutinin titer may occasionally be so high as to make testing of the patient's red cells for type difficult, owing to the small amount of hemagglutinin adsorbed to the red cells. This can usually be obviated by several washings of the patient's red cells with isotonic solution of sodium chloride.

It is well to remember that transfusions in cases of acute hemolytic anemia may be followed by severe reactions, although these may be diminished by the use of a careful cross matching technic. Thus as few transfusions as possible should be given, chief reliance being placed on the recuperative powers of the person's bone marrow. Since the hemagglutinin functions chiefly below 37 C, it is recommended that the blood be kept

continuously warm from its first removal from the donor's circulation. It is best not to use bank blood, since the red cells are already more or less modified and thus more liable to injury. Alkalization with solution of sodium carbonate intravenously as recommended by DeGowin and his associates¹⁵ may be of value in reducing the severity of the renal reaction.

The development of renal shutdown in some cases of acute hemolytic anemia is probably due to agglutination of red blood cells within the glomeruli and subsequent blockage of renal tubules, as with incompatible transfusion reactions. If anuria occurs, death may result, but milder degrees of renal impairment have been evidenced in a number of cases by an increase in the nonprotein nitrogen concentration of the blood¹⁶. It is possible that death from uremia has in some cases been erroneously thought to be due to precipitation of the drug or its acetylated derivative in the renal tubules.

The appearance of spherocytosis and increased hypotonic fragility in experimental and acquired hemolytic anemias has already been commented on in previous papers. The conception that spherocytosis represents an inherent fault in red cell formation in the bone marrow has been adequately disproved through both experimental and clinical observations¹⁷. We have shown that the spherocyte is a mature red cell which has been injured by the activity of a hemolytic agent. Thus spherocytosis, long considered pathognomonic of familial hemolytic jaundice, may occur in various hemolytic syndromes and—as in these cases—in the initial and active stages of the acute hemolytic reactions associated with the sulfonamide compounds.

A word regarding terminology. The type of abnormal isoagglutinin described is active not only against all types of human red blood cells but against those of the patient and to some extent against those of other animal species. Thus it might be called a "panagglutinin," although the term autoagglutinin has usually been used. Since the various terms have often been indiscriminately and interchangeably used and since the agglutinins are generally more effective at temperatures lower than 37 C, it is suggested that the term "cold hemagglutinin" be utilized.

SUMMARY

Severe hemolytic reactions occurred in 3 cases of acute infectious disease in which sulfadiazine and sulfathiazole had been used. They were associated with the presence in the blood of potent cold hemagglutinins, which were also active against the patient's own red blood cells (autoagglutinin). In 2 cases, so-called virus pneumonia was present, in the third a case of infectious mononucleosis, potent heterophile sheep cell agglutinins were also found. It is probable that both the drug and the hemagglutinins were causally related to the sudden development of intravascular hemolysis with hemoglobinuria and acute hemolytic anemia. Recognition of the presence of a cold hemagglutinin is important both diagnostically and therapeutically, especially from the standpoint of possible transfusions. Chilling of the patient with "virus" pneumonia should be avoided.

ACUTE TOXIC NEPHROSIS

A CLINICAL AND LABORATORY STUDY BASED ON A
CASE OF CARBON TETRACHLORIDE POISONING

A C CORCORAN MD

R D TAYLOR MD

AND

IRVINE H PAGE, MD

INDIANAPOLIS

Acute parenchymatous renal injury results from the toxic action of a large number of unrelated substances. Their classification is neither easy nor indeed rewarding for in most instances the clinical pattern of the poisoning is very similar. Even the microscopic differences in the kidney are not very great. Mercurial nephrosis is selected by Fishberg¹ as the typical instance of this type of renal disease, it is of course the one most frequently seen in practice. Nephrosis due to ethylene glycol, dioxane tartrates and the like is much less common. The renal lesions that develop during cholemia or after intravascular hemolysis or burns or crushing injuries should also be considered under this general heading, since they share a "toxic" cause and a common clinical pattern of proteinuria, oliguria, edema, hypertension and azotemia with more or less characteristically depressed consciousness, and at autopsy the kidneys show epithelial degeneration.

The present report is an analysis of events in a case of renal injury due to the inhalation of carbon tetrachloride. Our purpose is to associate the renal, cardiovascular and symptomatic expressions of toxic nephrosis. We realize that carbon tetrachloride is not often thought of as a renal poison and that, like every other poison, it has certain distinctive features. Still the course of the disease in this patient is so like that in most cases of toxic nephrosis of moderate severity that the observations made can apply generally.

METHODS OF STUDY

The course of the renal lesion was followed by (1) routine urinalyses, (2) measurement of urinary output, (3) determinations of blood urea nitrogen and (4) urea clearance, (5) estimation of urinary concentrating power and count of the urinary sediment by the method of Addis² and (6) measurement of the plasma clearances of diodrast and inulin and of functioning tubular secretory capacity for diodrast (T_{mp}).

Measurements of diodrast and inulin clearance and T_{mp} were made substantially as described by Smith, Goldring and Chasis³. Diodrast-iodine and inulin in plasma and urine were determined by the methods of Corcoran and Page⁴.

The patient was referred to the authors by Dr Emmett B Lamb from the Lilly Laboratory for Clinical Research Indianapolis City Hospital.

Assistance was given the authors by Mrs E Bowers Alward RN, Mr Truman Woodmansee BS, Miss Mary J Armstrong BS and other associates in the Lilly Clinic.

Cardiovascular changes were demonstrated by (1) determinations of arterial pressure (twice daily during hospitalization), (2) clinical examination of the heart, retinal vessels and other organs, (3) electrocardiography (4) thoracic fluoroscopy and roentgen orthocardiography and (5) ballistocardiographic measurement of cardiac output (method of Starr, Rawson, Schroeder and Joseph⁵).

The general clinical study was based on a careful history and physical examination, daily observation of progress during hospitalization and frequent examination thereafter.

PROTOCOL

A white man aged 36, a welder, spent four hours straightening and welding a bent gasoline tank into which he sprayed carbon tetrachloride from time to time to prevent an explosion. At midnight, when he finished, he felt weak and nauseated and, although it was a cold winter night, he had to keep his car window down to keep awake on the 2 mile drive to his home. He went to bed at once and was awakened in about four hours by excruciating headache and generalized painful muscular stiffness at which time he also noticed difficulty in breathing. He vomited copiously that morning, and for three days he did not eat or drink because of immediate and violent emesis on swallowing. He did not void more than

Chart 1—Clinical course in a case of toxic nephrosis due to carbon tetrachloride and special observations on the peripheral blood vessels. The observations extend over a period of ten weeks. The blood pressure measurements indicated between the second and seventh weeks are weekly averages of two daily readings. Cardiac index = cardiac output per square meter per minute. Peripheral resistance is calculated from mean arterial pressure and cardiac output. The bases of the observations are described in the text.

1 or 2 teaspoons of dark urine during the first two days and a cup more or less on both the third and fourth days. He passed about a pint of urine on the fifth day. He was able to eat a small amount that day also. His nose bled on the fifth day for several minutes, but he tried to go back to his work. He found that weakness and muscle pain—particularly in the back of the neck—prevented him working more than one hour. The sixth day he noticed that his ankles and eyes were puffy and his abdomen was distended. Proteinuria was discovered. He had eaten little because of anorexia and occasional vomiting but by the ninth day had gained about 15 pounds (68 Kg) over his normal weight. His blood pressure that morning was 180/114 at a routine examination six months before it had been found to be 130/90 and it was only 118/72 on the first day of his illness.

On admission to the Lilly Clinic on the ninth day of illness he was obviously very ill. His conjunctivae were hyperemic, his face body and extremities were pasty and bloated and his voice was hoarse. He complained greatly of pain along

5 Starr Isaac Rawson A J Schroeder H A and Joseph N R Studies on the Estimation of Cardiac Output in Man and of Abnormalities in Cardiac Function from the Heart's Recoil and the Blood's Impact the Ballistocardiogram, Am J Physiol 127 128 (Aug) 1939

the ligamentum nuchae and moderately of difficulty in breathing. His nose showed evidence of recent minor epistaxis. The optic disks were slightly reddened and the retinal arteries and arterioles constricted (grade 1 plus). Nothing abnormal was revealed by examination of the heart and lungs. The thrust of the apex beat was increased (grade 2 plus). The blood pressure was 174/114. The abdomen was moderately distended with fluid and gas. The liver was not palpable.

In spite of the absence of physical abnormalities in the chest a roentgenogram showed a small amount of fluid in both pleural cavities and the lung markings were increased in a manner which suggested irritative pulmonary edema. The heart and great vessels were not abnormal. An electrocardiogram (eleventh day of illness) showed a low QRS complex in the three standard and one (CR 4) precordial leads. The R wave of lead CR 4 measured 0.5 mm. The changes were interpreted as myo-

The results of some of these, and of other examinations, are shown graphically in the accompanying charts and some of them are tabulated.

An unexpected finding was made on the twenty-fifth day of the illness when, in connection with another study, the patient was given 0.2 cc of 1:5,000 epinephrine intravenously with an immediate resultant rise in arterial pressure from 160/100 to 270/140. The pressure remained at this level for about ten minutes and was maintained there by four succeeding doses of 0.2 cc during the next twenty minutes. The pressure fell slowly during the next half hour, but the patient continued to complain of severe headache and nervousness for twelve hours after the injection. In comparison with other normal subjects observed during this study, this patient's sensitivity to epinephrine was more than five times greater.

The course throughout the period of observation was one of progressive improvement, with apparent complete recovery at the end of about two months. An adequate diet was supplemented with a vitamin preparation, in addition, 400,000 units of vitamin A was given daily during his three weeks of hospitalization. The extra vitamin A was given empirically because of the increased renal function which sometimes appears in hypertensive patients during treatment with this substance.⁶ No other special treatment was given.

COMMENT

The interest of this case falls under two headings: (1) the significance of carbon tetrachloride as the specific intoxicant and (2) the general characteristics of toxic nephrosis which it exemplifies.

Carbon Tetrachloride Nephrosis—This topic has been recently reviewed in some detail by Smetana⁷ and will be touched on here only because it is neither widely nor sufficiently realized that carbon tetrachloride is capable of causing renal injury. In his review, Smetana collected reports of 141 cases of carbon tetrachloride poisoning, in 33 of which renal symptoms were present. It appears that the probability of toxic nephrosis is doubled when the intoxication occurs by inhalation rather than by oral ingestion, since 27 of the 33 cases of renal injury developed among the 99 cases in which exposure was respiratory.

The symptoms and laboratory findings of this condition have been tabulated by Hagen, Alexander and Peppard.⁸ Briefly, it is distinguished by (1) immediate effects of narcosis reflecting injury to the central nervous system and irritation of mucous membranes, (2) delayed effects (twelve to thirty-six hours) including headache and mucosal irritation (respiratory, conjunctival, gastric) with hepatitis and a curious painful muscular rigidity, and (3) late effects (two to eight days) including the foregoing with evidence of a hemorrhagic diathesis and toxic nephrosis (proteinuria, oliguria, hematuria and cylindruria) with generalized edema, hypertension, clouded mental state and azotemia. The case reported by them is that of a man who inhaled the fumes of carbon tetrachloride after its use as a fire extinguisher. Definite evidence of hepatic damage developed but otherwise his general course was very like that of our patient. Indeed, it has been suggested⁹ that the symptoms are sufficiently characteristic to prompt inquiry as to exposure to this chemical in the absence of a definite history.

It will be gratifying if the industrial exposure of unskilled workers during the present acceleration of

Chart 2—Special observations on the kidneys

cardiac damage consistent with anterior cardiac infarction. An electrocardiogram on the twenty-sixth day was entirely normal.

His blood showed 409 million red and 11,400 white blood cells per cubic millimeter, hemoglobin was 66 per cent of normal. Plasma bilirubin was 0.5 mg per hundred cubic centimeters and the icterus index normal. The urine contained a trace of urobilinogen. Plasma protein content was 5.9 Gm total and 3.7 Gm albumin per hundred cubic centimeters. He excreted 0.38 Gm of hippuric acid during one hour after the intravenous administration of 1 Gm of sodium benzoate on the tenth day. At this time the blood urea nitrogen was 73 mg per hundred cubic centimeters and urea clearance about 5 per cent of normal. On the twenty-sixth day the hippuric acid excreted during the test amounted to 1.1 Gm.

An Addis test done on the twenty-first day of illness revealed a maximum nonprotein urinary specific gravity of 1.014, a protein content of 12 Gm in twenty-four hours and excretion of red and white blood cells and casts within normal limits.

production does not result in other similar cases. Fortunately recovery nearly always occurs. It is usually considered to be complete but we believe that ours is the first case in which a detailed study of renal function has been done and convincing evidence obtained of renal restitution to integrity.

The insignificance of hepatic damage is particularly striking in our case in view of the severe renal disease. The patient had not been jaundiced at any time during his illness. On the ninth and tenth days there was neither clinical nor chemical evidence of hepatic injury. If the presence of only a trace of urobilinogen in the urine is ascribed to failure of excretion by the coexistence of severe renal with mild hepatic damage, still the hippuric acid test indicates normal hepatic synthesis from the sodium benzoate when the amount excreted is corrected for renal damage in the manner suggested by Kohlstaedt and Helmer,⁹ i. e. by reference to the concurrent urea clearance.

Since carbon tetrachloride may form phosgene on heating, persons exposed to its heated fumes as was our patient, may have the complication of phosgene poisoning in the mucosal and pulmonary irritation which

ethylene glycol diiodane, burns, traumatic anuria and transfusion hemolysis). Here the injury seems to depend simply on the concentration of the toxin in the tubule fluid as the result of abstraction of water from it in the proximal tubule and loop of Henle. The injured cells swell and desquamate. At first, as during diabetic coma¹⁰ the tubular barrier may be functionally disorganized, so that its reabsorption is no longer selective. However this may be, the injured cells themselves may impede the flow of tubular fluid and the kidney swells, partly from their obstructive effect and partly from the interstitial reaction at their injured basement membranes. Interstitial pressure is increased and effective intraglomerular filtration pressure is correspondingly reduced, as is also the rate of renal blood flow.¹¹ The swelling subsides as recovery begins, renal blood flow and filtration rate are increased. The normal basic architecture and particularly the stroma of the kidney are well preserved. Restoration to integrity is therefore possible if the initial injury is not too severe. New epithelium is formed and its functions of secretion (as shown in the T_{mp}) and capacity for reabsorptive work (maximum specific gravity, chart 2)

Functional Changes in Toxic Nephrosis Due to Carbon Tetrachloride

Day of Disease	Effective Renal Blood Flow (HD) Cc	Plasma Diodrast Clearance per Min	Plasma Inulin Clearance	Filtration Fraction	T_{mp} Mg Diodrast Iodine per Min	HD/ T_{mp} Cc per Min	Maximum Urinary Specific Gravity	Cardiac Index 1 per Sq M	Blood Pressure Mm Hg
10	116	67.8	5.5	0.086	3.7	31.3		1.50	157
22	74	464	56	0.12	23.8	32.5	1.014	1.76	126

64	1170	649	128	0.20	65	17.2	1.030	2.64	116

Successive changes during toxic nephrosis in effective renal blood flow (calculated from diodrast clearance and hematocrit index) inulin clearance, filtration fraction (inulin/diodrast clearance ratio), maximum tubular capacity for secretion (T_{mp}), maximum nonprotein urinary specific gravity, the apparent volume of blood flow per unit of functioning tubular mass (HD/ T_{mp}), cardiac index (liters of cardiac output per square meter of body surface per minute) and blood pressure (mean of systolic and diastolic brachial pressure). The values of clearance and T_{mp} are expressed as cubic centimeters or milligrams per minute per 1.73 square meters of surface. The values obtained in the fourth observation (64th day) are taken as normal.

usually develops. However, such irritation occurs even after exposure to the unaltered substance.

Toxic Nephrosis.—The renal injury which may follow exposure to toxic substances is of particular interest. Here, in contrast to acute Bright's disease, the injury is primarily epithelial and not vascular. Clinically, however, the syndrome differs only quantitatively from glomerulonephritis in its relationships of proteinuria, pyuria, cylindruria, oliguria, hypertension and edema. Since the nephron is the structural unit of renal function and damage within it, whether epithelial or vascular, extends to the whole nephron, the gross clinical and functional patterns of acute toxic nephrosis and acute glomerulonephritis are very similar.

The injury probably begins with contact of the toxin and epithelial renal cell at the cell's tubular surface, where the poison is apt to be more concentrated than it is in blood or interstitial fluid. When the injury is largely to the cells of the proximal tubule as it is with mercury or tartrate, it may be that the toxins have been concentrated within the cell by active reabsorption much as is dextrose in this area. At least tubular fluid is still dilute at this point and the concentration of the toxin is probably not at a maximum. As would be expected the more common site of injury is the epithelium of the distal tubule (e. g. carbon tetrachloride,

recover together. A similar parallelism of concentrating power and T_{mp} exists in cases of essential and malignant hypertension.¹²

The order in which these changes developed is shown in the values of diodrast and inulin clearance and T_{mp} . The principles of their interpretation under normal conditions and in hypertension have been discussed elsewhere in some detail.¹³ It will suffice to note that inulin clearance (IC) is equivalent to the rate at which water is filtered off from the renal plasma through the glomerular capillaries into the tubules (normally about 120 cc a minute) while diodrast clearance (DC) is roughly equivalent to the rate at which plasma flows through functioning tissue, i. e. the volume of plasma from which filtration occurs (normally about 600 cc a minute). If inulin clearance is divided by diodrast clearance (IC/DC), the result, known as filtration fraction, expresses the proportion of plasma water squeezed

out through the glomerular capillaries by intraglomerular pressure (normal, about 0.18). The clearance of diodrast is much higher than that of inulin because most of the diodrast present in renal arterial plasma is removed in one renal passage, so that little or none remains in renal venous blood, in contrast to about 20 per cent of the inulin and 10 per cent of urea. This efficient excretion of diodrast is maintained, as long as the plasma concentration of diodrast is not too high, by active secretion of diodrast from renal interstitial fluid through the cells of the proximal convoluted tubule to the tubular fluid. At high plasma concentrations the secretory capacity is exceeded and the amount reaching the tubular fluid and thence the urine attains a maximum. Just as one might estimate the cars of a railroad in terms of the freight they can carry, so the maximum capacity to transfer diodrast is conceived of as a measure of tubular mass and, by abbreviation, referred to as Tm_D (normally about 50 mg of diodrast-iodine a minute³). The rate of effective renal plasma flow (DC) divided by tubular mass (Tm_D) expresses the rate at which plasma perfused that volume of renal tissue which can excrete 1 mg of diodrast as iodine, and if the effective renal blood flow has been calculated from the plasma flow and hematocrit index (H) the unit volume of renal blood flow may be similarly calculated as HD/Tm_D (normally, about 23 cc a minute).

In the present case, toxic nephrosis reduced effective renal blood flow (chart 2 and table) and caused a proportionately greater reduction in filtration rate and functioning tubular mass (Tm_D). From this it might seem as though a large increase in the volume of blood flowing to the units of uninjured functioning tubular tissue had occurred ($HD/Tm_D = 31$ and 32 cc a minute in observations 1 and 2). That this apparent hyperemia is not real is suggested by the coexistence of hypertension, increased peripheral resistance, retinal arterial constriction and low absolute level of effective renal blood flow. The explanation for it probably depends on diodrast entering the renal interstitial fluid through a set of capillaries attached to a nonsecreting and injured nephron and then diffusing over to be excreted by a secreting and uninjured nephron. Diodrast clearance thus comes to exceed the true level of plasma flow to functioning and secreting nephrons. The measurement of Tm_D , in which transfer capacity is fully saturated, is not affected and the result is a high level of diodrast clearance in relation to Tm_D . The process has been termed "vicarious hyperemia" by Smith¹⁴. Since in such cases as this there is probably no hyperemia but rather ischemia, perhaps the term "vicarious clearance" might better convey the meaning of an altered significance of diodrast clearance. As originally visualized with reference to the renal changes of essential hypertension, this process was due to formation of "impotent nephrons" which filtered but could not secrete. The parallel reduction of filtration rate and tubular secretory capacity suggests that in this case of toxic nephrosis both filtration and secretion were temporarily in abeyance in many nephrons.

Decreased filtration rate and filtration fraction are observed in eclamptogenic toxemia of pregnancy,¹⁵

experimental glomerulonephritis¹⁶ and acute and chronic Bright's disease¹⁷. In these conditions the glomeruli are known to show definite structural changes, and we have therefore tentatively attributed the decreased filtration rate and fraction to the formation of virtual shunts of blood through injured glomerular capillaries which are still canalized but no longer filter.

Others¹⁸ have observed this phenomenon in pre-eclampsia and eclampsia and attributed it to afferent arteriolar vasoconstriction or renal edema. Its presence in some cases of toxic nephrosis—we have observed it in a case of mercurial nephrosis but not in another due to oil of tansy¹⁹—suggests at least that it depends on another mechanism than glomerular injury or afferent constriction—most probably renal edema. This, with or without tubular obstruction by detritus, increases intrarenal pressure and thus decreases the effective pressure of filtration. "Vicarious clearance" alone does not explain the severe depression of filtration fraction here observed.

Whatever the cause of the reduction in glomerular filtration rate, among its results are oliguria and sodium retention, which together lead to edema. In acute Bright's disease and eclampsia additional widespread irritative vascular injury is postulated as a basis both of edema and of cardiac injury. It is, to say the least, doubtful whether such a factor plays a role in toxic nephrosis in which the injury is renal and not vascular but epithelial. The myocardial damage in our patient during his illness may therefore depend on some other factor than local vascular injury—possibly the acute hypertension which his heart was suddenly called on to maintain. A similar factor may play a role in eclampsia and acute Bright's disease.

The hypertension itself is of particular interest. As in most cases of toxic nephrosis, it did not develop in the first days of the renal injury, when renal blood flow is often greatly reduced,¹¹ but was delayed, perhaps until renal swelling had increased the intrarenal pressure. Such a view is in accord with the hypothesis that this hypertension is of renal origin and due to release of renin and formation of angiotonin in the blood²⁰ as the result of reduced intrarenal pulsation.²¹ The mechanism has its parallel in the experimental

19 On the third day of mercurial nephrosis a patient (B P) showed the following clearances: diodrast 246 inulin 23.5 cc per minute filtration fraction 0.09 Tm_D was 5.3 mg diodrast iodine, and dextrose Tm 37 mg per minute. Blood pressure was 144/94. This patient recovered but further observations were not made. Tabulated here are the findings in a patient suffering from toxic nephrosis due to ingestion of oil of tansy. The nephrotoxic action of this drug is not generally recognized.

hypertension of fibrocollagenous perinephritis described by Page²² in which also the renal parenchyma is compressed. Our patient's pronounced sensitivity to epinephrine—which on somewhat inadequate grounds is stated to be a general phenomenon in nephritis as compared to essential hypertension²³—may suggest that another pressor system may have been operating such as that described by Bing²⁴ in which renal anoxobiosis leads to formation of a pressor amine from dihydro- α -phenylamine. However, the existence of such pressor systems under conditions compatible with life has not been established.

The coincidence of decreased cardiac output and electrocardiographic evidence of cardiac damage might suggest that injury has decreased output by causing cardiac insufficiency. The ballistocardiographic record resembles that seen in essential and malignant hypertension²⁵ and, during intravenous administration of angiotonin, the effector substance of the renal pressor system²⁶. In cases of uncomplicated essential hypertension, as during administration of angiotonin or, apparently, toxic nephrosis, cardiac output decreases as peripheral resistance makes it more difficult for the heart to maintain a normal output and a greatly increased pressure. The decreased output is therefore more probably the result of incomplete cardiac adaptation than actual cardiac insufficiency.

SUMMARY

Because the essential lesion of toxic nephrosis is based on destruction of the epithelium of the nephron, its manifestations are much the same in spite of wide differences in the causative toxic agents. The clinical and functional characteristics of toxic nephrosis due to carbon tetrachloride, considered in detail in the report, therefore apply generally. The stroma of the kidney is left intact so that complete recovery may occur by epithelial regeneration. The clinical manifestations of edema, oliguria and proteinuria are associated with decreased renal secretory capacity and with decreased renal blood flow and glomerular filtration rate. Analysis of data from diodrast and inulin clearances suggests that the injury extends temporarily to both the secretory and the filtering functions of the nephrons. The hypertension is presumably of renal origin and due to release of the renal pressor system (renin renin-substrate angiotonin). The resultant increase in peripheral resistance rather than a specific myocardial injury is the presumptive cause of the decrease in cardiac output present during the persistence of hypertension.

Clinical recovery is associated with a reversal of all these changes and their return to normal. In the case presented renal damage was associated with pressor hypersensitivity to epinephrine.

BRONCHOSCOPY AND ASTHMATOID RESPIRATION

CAPTAIN STANTON A. FRIEDBERG
MEDICAL CORPS, ARMY OF THE UNITED STATES

Altered respiration of an asthmatoïd type may result from a variety of clinical conditions which produce changes in the caliber of the bronchial lumen. The term asthmatoïd respiration is used to imply a type of respiratory cycle in which the expiratory phase is accompanied by a wheezing sound similar to that heard in true bronchial asthma but for which there may be a number of different etiologic factors. My purpose in this paper is to indicate the diagnostic and therapeutic value of bronchoscopy in simulated asthmatic, or asthmatoïd breathing.

The initial impetus in the study of altered respiration, bronchoscopically considered probably stems from Chevalier Jackson's classic description of the "asthmatoïd wheeze".¹ Often quoted, the original words bear repeated emphasis: "The asthmatoïd wheeze may be defined as a sound heard by placing the ear in front of the patient's mouth during expiration. It resembles the wheezing of an asthmatic patient but is drier. It is caused by the vibration of the air passing the foreign body in the bronchus." Lukens² in 1925 described the bronchoscopic findings in bronchial asthma and was one of the earlier writers to suggest diagnostic bronchoscopy on almost all asthmatic persons.

The investigation of the tracheobronchial tree in order to rule out conditions which might simulate asthma has been advised by many authors. Jackson³ has reported a large series of foreign body cases in children erroneously diagnosed as asthma. Gaarde has been quoted as emphasizing that "to limit the study of the asthmatic patient to an allergic investigation, to investigation of the nose and throat, to a search for foci, or to a roentgenogram of the thorax, is to invite diagnostic and therapeutic failure".⁴ Clerf⁵ has pointed out that many patients present signs and symptoms which do not fit the textbook description of asthma and suggests "wheezing respiration" as a better term for atypical symptoms requiring endoscopic investigation. Consequently an ever increasing degree of attention is being directed to the importance of wheezing respiration in diseases other than bronchial asthma. Among these, foreign bodies in the air and food passages have been mentioned most frequently.³ Laryngeal pathologic changes, tumors of the trachea or bronchus whether benign or malignant,⁶ acute or chronic inflammatory processes involving the air passages, strictures or stenoses may cause altered respiration of an asthma-

toid type. The common denominator in all these conditions is a narrowing of the airway. To the bronchoscopist falls the role of interpreter for pediatrician, internist, surgeon and roentgenologist, although a cooperative effort on the part of all is prerequisite.⁸

The explanation for a wheezing type of respiration in most cases is to be found in a consideration of the normal physiologic movements of the bronchi during respiration. Elongation and expansion occur during inspiration. In expiration these structures contract and shorten. Thus a pathologic process which narrows or partially blocks the bronchial airway will interfere principally with the egress of air. Because of an abnormal irregularity of the lumen plus a physiologic bronchial contraction the vibration of the outgoing air will produce an altered expiratory sound. This sound is most often wheezing in character.

In an attempt to emphasize further the bronchoscopic aspects of simulated asthmatic, or asthmatoïd, breathing, the following case reports are presented.

REPORT OF CASES

CASE 1—J. O., a 2 year old boy, fell while eating popcorn and a momentary coughing spell ensued. Subsequently the child coughed frequently for several hours until brought to the Presbyterian Hospital. An expiratory wheeze was quite audible to the examiner's ear, 6 to 12 inches from the child's mouth. There was neither dyspnea nor cyanosis. A few wheezing rales were heard over both lung fields. Roentgenograms of the chest were normal.

Bronchoscopy was performed several hours later with a 5 mm. by 30 cm. instrument and without anesthesia. A shell-like object presented in the right main bronchus, one margin was apparently fixed to the medial wall, while the other, which was thin and frayed, moved with each expiratory motion. The wheezing expiratory sound was accentuated with the bronchoscope in situ. There was considerable diffuse tracheobronchitis. The free margin was grasped and rotated, and the object was removed. It was found to be a maize (popped corn) hull. No other particles were seen on completion of the examination.

On the following day there were scattered rales over both lung fields and a slight elevation of temperature. On the second postoperative day the chest was clear on clinical and roentgenographic examination, the temperature was normal and the child was discharged. There were no sequelae.

To the bronchoscopist the asthmatoïd wheeze and the history of a choking spell made a diagnosis of foreign body fairly obvious. A suggestion to defer bronchoscopy was disregarded because of the potential danger of vegetable matter in the tracheobronchial tree. The signs of partial or complete bronchial obstruction⁹ were absent, probably because of the exceedingly thin mobile margin of the hull and the fact that the tissue reaction had not reached its maximum.

CASE 2—V. C., a boy aged 16 months, was brought to the hospital for emergency treatment. There was an indefinite, though suggestive, foreign body history. There had been several periods of impending asphyxia with severe cough followed by subsidence of all symptoms except for a wheezing type of respiration. An asthmatoïd wheeze, grossly audible on expiration, was the only finding on entrance. The larynx was exposed without anesthesia and a foreign object was seen in the subglottic space. During inspection its position suddenly changed as a result of cough and inspiration. A small bronchoscope was introduced and one half of a hard nut shell (pistachio) was quickly removed as it lay across the bifurcation of the trachea. All symptoms disappeared and the child was discharged on the following day.

The history of a shifting type of obstruction, with alternate episodes of impending asphyxia and relative freedom, left little time for roentgenograms. The asthmatoïd wheeze was the all important indicator of some pathologic condition in the trachea. Shifting of the foreign body at the time of direct examination was doubtless a repetition of the events preceding admission.

CASE 3—E. B., a 4 year old girl, had been treated for asthma for one week without results. There was no history other than that the child had been well until two weeks prior and had since been having noisy breathing along with a progressively increasing difficulty in swallowing. Wheezing respiration was audible. Fluoroscopy disclosed the presence of a sizable metallic toy dog in the upper esophagus. The trachea was displaced anteriorly. On endoscopy much stagnant secretion was encountered in the pyriform sinuses and on entering the esophagus. The object was removed without trauma or undue respiratory embarrassment and the subsequent course was uneventful.

Only occasionally are esophageal foreign bodies of sufficient size to cause any considerable displacement of the trachea. The wheezing respiration in this case resulted from encroachment on the membranous posterior trachea with narrowing of the lumen and an overflow of secretions from an obstructed esophagus.

CASE 4—M. S., a 6 year old girl, had been having episodes of coughing and wheezing for six months. There was a family history of allergic disturbances. When first seen, her appearance was that of a child experiencing a typical asthmatic attack. There was a slight anemia and an elevation of the white blood count to 15,000 per cubic millimeter with 78 per cent polymorphonuclear forms, 20 per cent lymphocytes and 2 per cent eosinophils. Roentgenograms disclosed an area of increased density in the left lung with atelectasis of the lower lobe and fixation of the left diaphragm.

On bronchoscopy the mucosa of the left main bronchus was observed to be reddened and hypertrophic. Near the termination of this bronchus there was a definite narrowing which yielded on passage of the tube. A black foreign object was encountered and was displaced slightly by the suction tip, resulting in the outpouring of a profuse foul secretion. The object was engaged with a side curved forceps but crumbled immediately. Black fragments were removed, other pieces came away with suction and coughing. All evident particles were removed and thorough aspiration was carried out. The entire mass was sent to the laboratory. Positive tests for iron and traces of lead were obtained. Because of one minute intact metallic fragment, it was concluded that the material represented the corrosive products of an iron carpet or upholstery tack. Subsequent bronchoscopic and roentgenographic studies showed complete resolution of the pulmonary pathologic condition and the child has been free from "asthma" for one year.

Asthmatic symptoms, present for six months, were outstanding and the familial allergic history was misleading. The findings were those of partial bronchial stenosis due to the prolonged sojourn of a foreign body, corrosion of the object with bronchial obstruction, atelectasis and the typical "drowned lung." All symptoms and findings disappeared on removal of the offending agent.

CASE 5—Mrs. G. B., aged 38, had been troubled by a cough and wheezing at night for several months. The symptoms were progressing in severity and no conclusions could be drawn as to the cause. An investigation of allergic factors proved negative. There was no evidence of any contributory pathologic condition in the upper air passages. Roentgenograms of the chest were interpreted as normal. The patient insisted that her wheezing respirations were aggravated by lying on her left side and this was confirmed clinically. There were no physical signs of altered breath sounds except for a grossly audible asthmatoïd wheeze.

Reddening and thickening of the mucosa of the left main bronchus were noted. A foreign object was encountered at

⁹ Jackson, Chevalier, and Jackson, C. L. *Bronchoscopy, Esophagoscopy and Gastroscopy*, Philadelphia, W. B. Saunders and Company, 1934, p. 182.

3 cm from the tracheal bifurcation. Several fragments of calcareous material were obtained and the entire mass was then removed with a side curved forceps. The object proved to be an irregular broncholith measuring 1.5 by 1.25 by 0.75 cm. A biopsy specimen of the adjacent thickened mucosa was obtained.

The broncholith was radiopaque. A chest film taken following bronchoscopy appeared identical to the original film. The reason for failure to observe the stone roentgenographically was thought to be its proximity to the dense hilar shadows.

Microscopic examination of the bronchial mucosa disclosed a chronic inflammatory reaction with hemosiderin particles engulfed in numerous macrophages.

The patient has been free from all asthma-like symptoms for fourteen months. After careful questioning she recalled a severe coughing spell which occurred while eating Christmas dinner two years previously. The effects of this attack lasted several hours. The possibility of her having aspirated food particles which formed the nucleus of the broncholith has been the only etiologic factor thus far available. The subject of broncholiths and stone asthma has been well described by Pendergrass and de Lormier.¹⁰

Although this patient's symptoms were those of typical bronchial asthma with accentuation of discomfort during cold weather and at night one suggestive discrepancy was the aggravation which resulted on lying on her left side. The negative roentgenogram was misleading but fortunately not dissuasive. This and the preceding case would seem to support the rather radical contention of some authors that every case of asthma is entitled to diagnostic bronchoscopy.

CASE 6—Mrs. R. S. aged 41, had been having bronchial asthma of an allergic nature for thirteen years. While on vacation she suddenly developed pain in the left chest and a productive cough. This was not preceded by any choking episode, respiratory infection, dental care or illness of any type. When brought to Chicago there were physical and roentgenographic findings of a rapidly cavitating abscess of the left upper pulmonary lobe. Bronchoscopy was requested three weeks after the onset of symptoms. Inspection of the left main bronchus and upper lobe orifice revealed no evidence of obstruction. Passage of a flexible catheter and aspiration of a large quantity of foul secretion from the left upper lobe resulted in subsidence of the daily temperature elevation. External drainage of the cavity was carried out because of the persistent cavity. The diagnosis was anaerobic pulmonary abscess; contributory cause unknown.

This case is of interest for several reasons. Considering the prevalence of bronchial asthma with its attendant bronchial and bronchiolar obstruction from edematous mucosa and mucous plugs, atelectasis and lung abscess are infrequent complications. Bronchiectasis is more commonly associated with asthma and may have its inception in atelectasis but Clerf¹¹ is a result of wide experience, stated that he could not recall having seen or heard of lung abscess secondary to bronchial asthma. In view of the apparent benefit from bronchoscopy in this case and the well known salutary effects on early lung abscesses it is interesting to speculate on the outcome had endoscopic drainage been performed at the onset of symptoms or shortly thereafter. Finally bronchoscopy was an important element in the exclusion of organic or accidental bronchial obstruction as a predisposing etiologic factor.

CASE 7—A. C. a man aged 48 had been troubled by a mucous productive cough for about five years. At times there would occur episodes of asthmatic breathing followed in several days by the expectoration of considerable purulent secretion.

Bronchoscopy during one of the asthmatic spells disclosed a stenosis of the left lower lobe bronchus through which only a thin aspirator could be passed. There was a generalized chronic tracheobronchitis. Improvement in symptoms followed the procedure. Bronchograms subsequently verified the impression of bronchostenosis. The lingula branch of the left upper lobe also was involved.

Studies on this patient could not be continued but it was my impression that the situation was analogous to the type of bronchostenosis described by Prickman and Moersch.¹² Though the patient had a chronic cough asthmatic breathing appeared only at intervals and seemed to be on the basis of bronchial narrowing.

CASE 8—Mrs. L. F. aged 32 had been under treatment for pulmonary tuberculosis for two years. An exacerbation of symptoms including periodic attacks of wheezing respiration was responsible for a request for bronchoscopic study. Examination disclosed an infiltrating tuberculous lesion just above and involving the primary subdivisional area of the left main bronchus.

Bronchoscopy is now regarded as an indispensable adjunct in the treatment of tuberculosis. The ever widening concept of endoscopy is borne out by the realization that only a short time ago pulmonary tuberculosis was looked on as a contraindication to the procedure.

SUMMARY AND CONCLUSIONS

1 Altered respiration of an asthmatic type may result from a variety of clinical conditions which produce changes in the caliber of the tracheobronchial lumen.

2 Pathologic narrowing of the bronchial lumen coupled with physiologic shortening and contraction of the bronchi, probably combine to produce an abnormal vibration of the outgoing air during expiration. The resultant sound is often wheezing in character.

3 Illustrative cases indicate the diagnostic and therapeutic value of bronchoscopy in simulated asthmatic breathing.

4 Endoscopic investigation is warranted in any case of atypical bronchial asthma which does not respond readily to diagnosis and therapy.

Immersion Foot—Submarine warfare has focused attention on immersion foot—a vascular disease of the extremities due to exposure. This condition seen in survivors from ships torpedoed in the cold waters of the North Atlantic is in no way different in its etiology and pathology from the trench foot observed in the last war. In either case the lesion is caused by temperatures sufficient to chill but not to freeze the tissues. Experimentally exposing an extremity to cold causes formation of edema fluid with a relatively high protein concentration. This is interpreted as meaning that cold is sufficient to freeze the tissues can produce an increase in capillary permeability and an inflammatory exudate. The edema formation is roughly proportional to the degree of cold and to the duration of exposure.

Shipwrecked sailors exposed to cold for prolonged periods develop swollen, discolored, anesthetic and even pulseless extremities, the distal portions usually being affected most severely.

Men habitually exposed to warm environments such as those of the Mediterranean and African races and those employed in boiler rooms apparently are more susceptible than others to immersion foot but there is no evidence that this susceptibility is due to a preexisting vascular abnormality. However one episode of immersion foot apparently renders the feet less resistant to further exposure to cold. Wilkin Robert W. and Friedland Carl K. Peripheral Vascular Disease. *New England J. Med.* July 1 1943.

Clinical Notes, Suggestions and New Instruments

ARACHNODACTYLY COMPLICATED BY DISLOCATED LENS AND DEATH FROM RUPTURE OF DISSECTING ANEURYSM OF AORTA

MAJOR LEWIS E ETTER
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND

L PELIMAN GLOVER, M D, ALTOONA, PA

An interesting syndrome called Marfan's disease for the French physician of that name who first drew attention¹ to it in 1896 was encountered in a young man in the course of our examination of selectees at this station. The descriptive name arachnodactyly was given to the syndrome by another Frenchman, Achard,² because of the spider-like appearance of the extended fingers. Of unknown etiology, it has been described

as being both familial and hereditary. As the dystrophy affects skeletal muscle structure as well as visceral organs, it has been thought by some to arise from an embryologic defect in the mesoblastic tissue, and by others to be due to faulty secretion by the hypophysis.

In discussing two additional theories of origin, namely germinal and due to "status dysraphicus," Marfan³ concluded that not any are satisfactory and all can be assailed by critics.

Our subject was a youth of 21, eldest of a family of five children, who was born in Brazil of German parents, each of whom is healthy. It was first noticed that he had trouble with his eyes at about 9 years, and he had been wearing glasses since that time. He had always been tall for his age and grew unusually fast.

At the age of 14 he first developed pains in the muscles and joints, but the attack was not sufficiently severe to cause him to stay in bed. This was passed off as being due to growing pains and it was not until seven years later that symptoms of heart disease were manifested. These first came on as breathlessness and pains in the chest, precordium and neck.

Besides the parents there are three brothers and one sister living and well. We examined the younger brother, aged 15, who was tall for his age (69 inches, or 175 cm) but could

find no evidence of eye, skeletal or visceral defect. The other children were of average size and development.

His physiognomic features showed most of the typical findings of the syndrome, namely bossing of the frontal eminences, prominent supraorbital ridges, protrusion of the upper half of the ears, large chin, high arched palate, long slender teeth, very long hands and feet, small amount of subcutaneous fat and pronounced degree of muscle hypotonia with ligamentous relaxation.

The degree of ligamentous relaxation (double jointedness) was extreme in this case as the boy could lock both his legs behind his head and lay his thumb back along the wrist and across the inside of his closed fist with the distal phalanx protruding.

Some of these features can be noted in the accompanying photograph taken within a year before his death (fig 1). The height and elongation of extremities is well shown, particularly the spider-like appearance of the left hand as it is extended. He wore size 11½ shoes.

He was 76 inches (193 cm) tall and weighed 165 pounds (75 Kg). There was no scoliosis, kyphosis or lordosis as is often observed in these cases, but the costochondral ridges were prominent and he was pigeon breasted.

Physical examination showed, in addition to the foregoing, the rather unusual finding of essentially normal vision in the right eye with visual acuity of 20/50 corrected to 20/30 (myopia) and a normal lens and eyeground. The left eye showed a normal ocular rotation and no squint. The globe was equal to the right in size. Vision was limited to counting fingers at 5 feet. The pupil was round. On dilatation the lens was

Fig 3—Metacarpals and phalanges elongated with spider like spread of digits. Epiphyses all closed.

subluxated downward and tilted slightly backward at 12. Congenital opacities were present in the periphery which partly caused the poor vision, correction coming only to 20/200. 11° optic nerve and fundus were negative.

A report secured from an optometrist who first examined the boy in February 1939 gave vision in left eye corrected to 20/200 by 2.25 cylinder axis 120. He did not notice a subluxated lens at that time. (About 50 per cent of the cases show a

abnormality as dislocation of the lens of the eye often bilateral, and pathologic change in the structure of the heart, either congenital or acquired from rheumatic infection⁴)

The remainder of his physical examination was essentially negative except for findings in the cardiovascular system. He was found to have all the classic signs and symptoms of aortic insufficiency. The cheeks were pale and the pulse was of the collapsing water hammer type.

Examination of the chest showed a heaving precordium with the point of maximum impulse in the sixth interspace, anterior axillary line. There was a slight systolic and loud diastolic murmur at the base of the heart and aortic orifice transmitted into the neck and to the left of the sternum.

Capillary pulsations were present in the finger nail beds, and Duroziez's sign could be heard over the femoral and brachial arteries. His blood pressure measured in millimeters of mercury was 140 systolic and 30 diastolic.

The liver and spleen were not enlarged and there was no edema of the extremities. Functional capacity might be graded class III (New York Heart Association). Laboratory examination showed blood Wassermann reaction and urinalysis negative.

Roentgenographic examination of the heart in the antero-posterior view showed no definite evidence of aneurysm except

Five days after our examination here, while the youth was sitting in a classroom of a radio school in Philadelphia, he suddenly collapsed and died instantly. An autopsy report furnished us by the coroner of Philadelphia County revealed aortic valvular regurgitation with pronounced enlargement of the heart and massive hemopericardium, chronic dissecting aneurysm of the ascending arch of the aorta with acute fatal rupture into the pericardial sac.

COMMENT AND SUMMARY

It has been stated by most authors that a characteristic feature of Marfan's disease has been some weakness of the cardiovascular system, frequently congenital valvular disease or valvular disease as a sequel to rheumatic polyarthritis. In none of the cases so far reported has a complication such as seen in this case been noted. Autopsies in these cases are rare, ours being the fifth reported to date. Fletcher and Southworth⁴ have briefly reviewed the 3 previously reported, and Rambar and Denenholz⁵ described a fourth in which no congenital cardiac or pulmonary anomalies were noted.

The patient gave a history of rheumatic fever in early childhood and to this cause is attributed our finding of aortic valvular disease, of which he had all classic symptoms. The aortic incompetence was no doubt responsible for the loud diastolic murmur heard at the base of the heart, but it has been pointed out that this can occur in cases of dissecting aneurysm without actual impairment of the semilunar valves⁶.

The roentgenographic features of dissecting aneurysms are usually not pathognomonic. The close approach of the aortic and right auricular tangents in this case suggest extension of dissection along the ascending aorta, which is definitely widened at this point. Although the patient had all the signs of aortic regurgitation, the heart was not definitely of aortic configuration.

A frequent finding in dissecting aneurysms was noted in this case in that the youth gave a history of onset of his heart trouble seven months prior to death by pain in the precordium and chest radiating to the neck. This was followed by one to two hours of unconsciousness from which he recovered without a definite cause other than valvular heart disease being discovered. It is possible that this episode marked the onset of the tear and subsequent dissection of the aneurysm causing death.

EMPHISEMA OF THE ORBIT

A STUDY OF SEVEN CASES

CAPTAIN WILLIAM O. LINHART
MEDICAL CORPS ARMY OF THE UNITED STATES

According to Bray,¹ orbitopalpebral emphysema is not a very common condition, but when found it is always of traumatic origin and secondary to a fracture of the nasal orbital wall. Contusion over the orbital area with resultant driving of the eyeball into the orbit and recession of the orbital fat to one side may alone result in fracture by direct contact of eyeball and orbital wall. The common points for this type of fracture are in the lacrimal and ethmoidal bones. The lamina papyracea of the ethmoid bone a smooth very thin quadrilateral plate which encloses the ethmoidal cells and forms a large part of the medial wall of the orbit is the most logical point of fracture.

After fracture on blowing the nose or sneezing nasal pressure is built up so that air is forced into the orbital cavity or even into the lids if the pressure is great enough to penetrate the tarso-orbital fascia. Fuchs² states that the mere presence of a communication between the orbital tissue and a pneumatic

Fig. 4.—Metatarsals and phalanges elongated with characteristic inward deviation of terminal phalanges of outer three toes.

the disturbance of the aortic and right auricular tangents⁵. This resulted in absence of the normal indentation between the right auricle and the ascending aorta in the cardiac silhouette (fig. 2). There was a smooth edged slightly concave shadow extending into the neck suggestive of extension of the aneurysm along the innominate artery such as seen in 1 case described by Wood, Pendergrass and Ostrum⁶. There was loss of the normal concavity of the left cardiac border. The transverse cardiac diameter was just within the upper limits of normal with beginning enlargement of the left ventricle. The lungs were clear.

Films taken of the hands and feet showed the spider-like spread of the digits (figures 3 and 4). The metacarpals, metatarsals and phalanges were unusually elongated but it will be noted that all epiphyses were closed. A characteristic feature is seen in the inward deviation of the terminal phalanges of the outer three toes.⁷

⁷ Stewart J. M. A Case of Arachnoidectomy. Arch. Dis. Childhood 11: 64 (March) 1930.

cavity is not sufficient to produce the emphysema but that occasionally blowing of the nose alone will produce it. Diagnosis of orbitopalpebral emphysema is relatively easy, since there is usually a history of trauma along with the characteristic crackling feeling of air under the skin. If the lids are grossly involved there is considerable swelling with little or no inflammatory signs and with very little tenderness

Fig. 1 (case 1) —Mottled appearance, left orbital region, significant of emphysema

Fig. 2 (case 3) —Opaque left maxillary sinus emphysema of left lower lid

pannusitis in case 2. Patient 3 had a very fine fracture line in the left malar bone anterior and lateral to the left maxillary sinus. In addition the left maxillary sinus was opaque, indicating the probable presence of blood (fig 2). Patient 5 showed rather pronounced evidence of emphysema in the upper lid and cloudiness of the left antrum. Whether the latter was due to recent injury or old sinusitis could not be determined by x-ray examination. It is interesting to note that 3 of the 5 patients given x-ray examinations had a cloudy antrum on the same side as the emphysema.

No definite roentgenologic evidence of fracture line in the ethmoid, frontal, maxillary or lacrimal bones could be seen in any case. Due emphasis must be placed on the great difficulty in making a definite x-ray diagnosis of any fracture of the medial orbital wall, particularly of the lamina papyracea. Pancoast, Pendergrass and Shaeffer⁴ state that fractures of the ethmoid bone are very difficult to diagnose roentgenologically, as they usually present only secondary evidence of fracture, such as interstitial emphysema or clouding of the ethmoidal cells.

Intranasal examination in each case of the cases in the series failed to disclose evidence of bleeding or fracture.

In every case the pupils dilated well with 1 drop of 1 per cent atropine except in case 3, in which 4 drops was required for full dilatation. Fundus examination was negative in every case.

The ciliary injection in case 3 and diplopia in case 4 were absent at the end of the fifth day.

The procedure followed in handling cases was as follows: gross examination, a stereoscopic x-ray film of the orbit, instillation of atropine until the pupil was well dilated, fundus examination, pressure bandage if necessary and admittance to the hospital. Each patient was cautioned not to blow his nose. The air was absorbed and no patient complained of ocular symptoms after the tenth day.

Clinical Summary of Cases Presented

Case	History of Recent Trauma	X ray Evidence of Fracture	Evidence of Ocular Contusion	Other Contusion Evidence	Gross Proptosis	Emphysema of Lids	Time Interval for Absorption	Complications
1	Yes	Emphysema of lid	None	None	None	Lower	5 days	None
2	Yes	Emphysema of lids	None	Slight ecchymosis of lids	None	Upper and lower	5 days	None
3	Yes	Emphysema of lid cloudy antrum fine fracture of malar bone	Slight ciliary injection and slight irregularity of pupils	Pronounced ecchymosis of lids	None	Lower	7 days	None
4	Yes	Emphysema of lids cloudy antrum	None	Diplopia on looking up and to right	Yes	Small amount upper and lower	6 days	None
5	Yes	Emphysema of lid cloudy antrum	None	None	None	Upper	6 days	None
6	Yes	No x ray	None	None	Yes	Small amount, upper and lower	5 days	None
7	Yes	No x ray	None	None	None	Upper and lower	7 days	None

ones who showed proptosis. Patient 3 had considerable ecchymoses of the left eyelids and tenderness over the superior and lateral orbital margins. This patient also was the only one who showed some degree of ocular contusion.

Five of the 7 patients had stereoscopic x-ray films of the orbit. All 5 showed x-ray evidence of emphysema. Two of these, patients 1 (fig 1) and 2 showed no evidence of fracture except for the emphysema. There was x-ray evidence of chronic

SUMMARY

Seven cases of orbitopalpebral emphysema were studied, all with a history of recent trauma. In 5 of the cases stereoscopic x-ray films of the orbit were taken.

No definite fracture lines could be demonstrated to communicate with the nasal cavity. There were no complications in any case.

THE PHLEBOMANOMETER A NEW APPARATUS FOR
DIRECT MEASUREMENT OF VENOUS PRESSURE
IN LARGE AND SMALL VEINS

G E BURCH MD AND TRAVIS WINSOR MD
NEW ORLEANS

The importance clinically as well as experimentally of quantitative venous pressure determinations is well known. With full realization of the value of venous pressure measurements, they are neglected because the apparatuses are difficult to use, are too bulky to carry as part of the physician's instruments of examination, are applicable only in fairly large veins and are difficult to clean and sterilize for subsequent use.

About four years ago, Burch and Sodeman¹ described a simple direct method for measuring venous pressure. The method has proved of value clinically and has been used more and more by others. But it like other direct methods which employ a column of a fluid as the manometer has the dis-

sensitivity of the brass bellows. The bellows is enclosed in a housing (c) constructed so that the bellows activates the needle when the former is expanded by increasing the pressure within. A lock nut (d) is used to lock the bellows support (c) in place once the bellows is adjusted, so that the needle returns

Fig 1—Diagram of the phlebomanometer. See text for details.

advantage of being difficult to carry, prone to spillage of the fluid in the manometer either during use or when being transported from place to place, hard to use and bulky. In order to overcome these disadvantages and to make the apparatus compact, easily portable and of a size to fit in the physician's medical bag, a new instrument which we have named the phlebomanometer was constructed. The desirable features of the previously described apparatus¹ were incorporated in the new one.

APPARATUS METHOD

The apparatus is illustrated in figures 1, 2 and 3.

The construction of the apparatus is diagrammatically represented in figure 1. It consists essentially in adapting the principles of the ordinary aneroid manometer used clinically for recording arterial blood pressure to a manometer sensitive enough to record venous pressure. The metal bellows in the former is replaced by a more sensitive brass bellows (a). The brass bellows is of such a sensitivity that a pressure of 680 mm. of water rotates the needle (b) almost completely around the dial. The dial is drawn and numbered to conform to the

Fig 2—The apparatus enclosed in a compact case approximately one third actual size.

Fig 3—The phlebomanometer ready for use.

to the zero mark on the dial when the pressure within the system is atmospheric. The relationship of the bellows to the gear levers and jewel bearings which rotate the needle is shown in the inset (d) which is an enlargement of the interior of d.

Mr C. Morgani Jr. constructed the apparatus.
From the Department of Medicine, School of Medicine, Tulane University and Charity Hospital of Louisiana.
¹ Burch C. E. and Sodeman W. A. A Direct Method for the Determination of Venous Pressure. Relationship of Tissue Pressure to Venous Pressure. J. Clin. Investigation 18: 31 (Jan.) 1939.

The bellows is connected with rubber tubing to a small rubber pressure bulb (*B*) enclosed in a metal housing (*g*) and to an adapter (*h*) to which is fitted a 25 gage hypodermic needle. The pressure within the system is varied by a screw clamp (*j*). Valve *k*, such as is found on the pressure bulb of any clinical arterial blood pressure recorder, is placed in the system, so that it is possible to return the pressure easily within the system to atmospheric, at any desired moment.

Figures 2 and 3 are reproductions of photographs of the assembled apparatus mounted in a box of about the size of the container used for the ordinary clinical aneroid arterial blood pressure recorder. The apparatus shown in the photographs is approximately one third the natural size.

The glass adapter and needle are dry and sterile and kept, until used, in a narrow bore test tube. The adapter is 10 cm long and has an outside diameter of 5 mm and a bore of 1 mm. The surface of the adapter is cross hatched at about 1 mm intervals.

USE OF THE APPARATUS

In use the sterile adapter and needle are removed from the sterile test tube and connected to the rubber tubing (*l*) leading from the recording portion of the apparatus. A 2 per cent sterile aqueous solution of sodium citrate, which is stored in 1 cc glass ampules, is drawn into the glass adapter by first closing valve *k* and creating a negative pressure within the system. This negative pressure is produced by unscrewing screw clamp *j* until the meniscus of a column of the citrate solution reaches about the middle of the adapter. The pressure within the system is returned to zero by means of the screw clamp. The needle is then inserted into the vein studied. The pressure of the blood within the vein slowly forces the meniscus of the citrate solution farther into the glass adapter. The pressure within the phlebomanometer is increased by compressing the pressure bulb (*f*) with the screw clamp until the meniscus ceases to move. This occurs when the pressure within the recorder is equal to the blood pressure in the vein. That pressure, the venous pressure, is then read off the dial (*m*).

COMMENT

Since the pressure is determined when the meniscus is not moving, the bore of the needle may be as small as 8 microns.² A small needle makes it possible to make measurements in very small veins. The veins should be at heart level or at a constant level for before and after studies if the studies are used for comparison. The capillary pressure in the adapter is 2 cm. This can be corrected by holding the adapter when inserting the needle into the vein so that the meniscus is about 2 cm above the surface of the vein.

The use of the apparatus is very simple. It is not necessary to have the recording apparatus at heart level. It may be placed on the patient's bed or on an adjoining table. It is necessary only that the vein, at the point of entrance of the needle, be at heart level or a constant level.

Only the glass adapter and needle are sterilized. The sterile 2 per cent aqueous sodium citrate solution is put up in 1 cc glass ampules to make it easier to handle and carry. Many successive venous pressure measurements may be made with 1 cc of citrate solution.

The entire apparatus is compact, being no larger than an ordinary clinical aneroid, arterial blood pressure manometer. It will fit easily in a physician's medical bag. The phlebomanometer obviates problems of spillage of fluids, injection of fluids into the veins, loss of blood, problems of sterilization, preparation of the apparatus for further use, and the like.

The fact that the phlebomanometer makes it possible to measure the pressure in small veins adds greatly to the advantage of the apparatus. Frequently it is desirable to know the pressure in structures such as the hands, feet, abdomen and face, where only small veins are found. This is encountered frequently in problems of diagnosis.

The phlebomanometer may be used to measure tissue pressure, spinal fluid pressure, intrapleural pressure or wherever a water manometer is needed. This obviates the purchase of more than one type of water manometer for these various clinical purposes.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER, Secretary

ULTRAVIOLET LAMPS FOR DISINFECTING PURPOSES

Introductory Statement

Clinical evidence submitted to the Council on Physical Therapy shows that under properly controlled conditions the killing of air borne micro-organisms by ultraviolet rays may be used to supplement other methods of disinfecting air for prevention of cross infection in contagious wards, in nurseries and for reducing air borne infection of wounds in hospital operating rooms. Council acceptance is limited to ultraviolet disinfecting lamps designed for installation in hospital nurseries, hospital wards and operating rooms.

Satisfactory evidence is not available to warrant acceptance of ultraviolet lamps for disinfecting solids. To kill a micro-organism a direct hit by ultraviolet rays of sufficient intensity is required. This is difficult to accomplish on the edge of a drinking cup, for example, also in a liquid containing suspended matter or in air laden with dust particles that shield the organism. Ultraviolet radiation cannot penetrate deeply and hence may be absorbed by finger marks, saliva, cosmetics or other foreign matter on a drinking cup. In view of the present available evidence, ultraviolet radiation appears to be an uncertain means of sterilizing solid objects (drinking cups, combs, brushes, shaving utensils, toilet seats and shoes) even if irradiation of the whole surface is possible. Ultraviolet lamps for disinfecting purposes are not accepted for disinfecting air in schools, waiting rooms, public gathering places and large halls. The evidence now available does not indicate that the incidence of colds can be reduced by the installation of ultraviolet lamps and by the irradiation of an enclosure occupied by people.

It is noted that a lamp used for disinfecting purposes is a single unit in an installation, and that compliance of the ultraviolet output of a single lamp unit with the Council's requirements does not insure adequate radiant disinfection or the safety of the occupants of the room in which an installation of such lamps is in actual use. Obviously the manufacturer and distributor of such lamps must assume some responsibility for the adequacy of the lamp installation for purposes of radiant disinfection of the air and for the adequacy of the protection from injury of the occupants of the space irradiated.

The total amount of direct and scattered ultraviolet radiation incident on the occupants must be kept below the level that will produce conjunctivitis, erythema and any other (at present unforeseen) injurious physiologic effects that may arise from prolonged irradiation. This requirement may be met by suitable arrangements of the lamp fixtures and baffles and not by requiring the applicants to wear glasses and special covering of exposed parts of the body (face, hands) normally uncovered. Hence, if the irradiation is of penetrating intensity, in a corridor of the hospital for example, care should be taken that the attendants do not receive an exposure which will cause injury to the skin or eyes, and particular attention should be taken to make sure that the intensity of the space at eye level through which a transient may pass or tarry momentarily will not cause injury to the eyes. Under no circumstances should the occupants of a room be able to look directly at the burner when standing within the region of potent intensity.

Ultraviolet lamps for disinfecting purposes shall have under suitable ventilating conditions of a room a concentration of ozone not to exceed one part in ten million.

Where there are aisles-ways and spaces between bed and wherever transient personnel carry on their work the ultraviolet radiation intensity shall not exceed 0.5 microwatt per square centimeter for a continuous exposure of eight hours and shall not exceed 0.1 microwatt per square centimeter for a continuous exposure of twenty-four hours per day.

² Landis E. M. Microinjection Studies of Capillary Blood Pressure in Human Skin, Heart 15:209 (May) 1930

The General Electric Germicidal Lamps manufactured by the General Electric Company Lamp Department, Nela Park, Cleveland have been mounted in fixtures manufactured by various firms. The burner or source of ultraviolet radiation and the different fixtures have been examined by the Council.

The characteristics of the General Electric Germicidal Lamps are given as follows:

	C E Germicidal 30 watt	C E Germicidal 15 watt
Glass types	974 glasses	974 glasses
Lamp watts — arc ballast	30 — 10	15 — 5
Length in sockets	6 in	18 in
Milliwatts 2 7 A	9 000—10 500	1 600—4 200
Max Int Microwatts/cm 1 m	100—117	40—46
Max Int Microwatts/cm 1 ft	740—840	300—340
Lamp life hours three hour operating intervals	2 500	2 500
Lamp life hour continuous operation	4 000	4 000

The ultraviolet radiation is confined almost entirely to the wavelength 2,537 angstroms. Fixtures should be designed and installed so as to insure little or no direct irradiation of the individuals in the rooms.

When first installed the radiant ultraviolet energy is considerably more intense than 20 microwatts per square centimeter at 1 meter, recognized by the Council as being the minimum intensity for acceptance. As the lamps age the intensity drops off rapidly at first and slower later on. Under ordinary usage the lamps maintain the acceptable minimum intensity or above for the guaranteed period of four thousand hours of continuous operation. If however, the lamps fall below this intensity before the guaranteed period has elapsed, the firm will make an adjustment on pro rata basis. Users of the equipment are advised to test the lamps each month to determine whether they are up to standard. Since the lamps burn at a characteristic color constantly there is no way of determining whether they are emitting sufficient ultraviolet radiation except by testing them with an ultraviolet meter.

The fixture manufacturers listed here have presented their products equipped with General Electric Germicidal Lamps, for consideration by the Council.

AMERICANARE ULTRAVIOLET GERMICIDAL UNIT

(Models UV-30, UV-15, Hospital Operating Room,
Ward and Nursery Models)

ACCEPTABLE

Manufacturer American Sterilizer Company, Erie, Pa

The Americanaire Ultraviolet Germicidal Unit is designed to irradiate the upper air of a room with ultraviolet radiation for disinfecting purposes. The unit is designed to be mounted on the wall above head level. An adjustable baffle protects occupants from direct irradiation.

A complete Americanaire assembly consists of a reflector housing a General Electric Germicidal lamp, a baffle and conductor cord and plug. Model UV-30 is 36 inches in length, 6 inches in width and 9 inches high. The input of the burner used in this model is 30 watts. Model UV-15 is 18 inches in length, 6 inches wide and 9 inches high. Input of the burner is 15 watt.

BURTON ULTRAVIOLET AIRRADIATOR GERMICIDAL UNIT

(Hospital Operating Room, Nursery and Ward Models)

ACCEPTABLE

Manufacturer Burton Manufacturing Company, 3855 North Lincoln Avenue, Chicago

The Burton Ultraviolet Airradiator Germicidal Unit is designed for the reduction of air borne bacteria and cross infection. The unit is equipped for wall mounting and includes a cord and plug set. The reflector is adjustable. The fixture is equipped with 30 watt General Electric Germicidal Lamp.

RADIAIRE

(Operating Room, Ward and Nursery Models)

ACCEPTABLE

Manufacturer Tru Aid Company, 1019 1023 North Madison Avenue, Los Angeles

The Radiaire, Model 991-15, produces ultraviolet radiation for disinfecting purposes. This model is designed for irradiation of operating rooms and hospital wards. The fixture is provided with removable baffles. Correct installation of the unit is said to insure little or no direct irradiation of individuals in the room being irradiated.

This unit was designed for and is used with, both the 15 watt and 30 watt General Electric Germicidal Lamp.

U-V-RAY AIR STERILIZERS

(Hospital Operating Room, Ward and Nursery Models)

ACCEPTABLE

Manufacturer Taft-Stern Company, Inc., 221 North LaSalle Street, Chicago

The U-V-Ray Air Sterilizers are designed for use in hospital operating rooms, wards and nurseries for the reduction of air borne bacteria. The burner housing is so mounted that only the air above head level is irradiated. Electrical equipment for the units includes toggle switch, auxiliary, replaceable starter and wire.

The U-V-Ray units were designed for and are used only with the General Electric Germicidal Lamp.

The Council on Physical Therapy voted to accept the foregoing ultraviolet lamps for disinfecting purposes and equipped with General Electric Germicidal Lamps.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ALVIN E. SMITH, M.D., Secretary

LIVER INJECTION (See New and Nonofficial Remedies 1943 p 392)

The following dosage forms have been accepted:

THE LEPJOHN COMPANY, KALAMAZOO, MICH

Liver Extract for Parenteral Use, 5 U S P Units per Cc. 2 cc ampul and 10 cc rubber capped vial. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

Liver Extract for Parenteral Use, 10 U S P Units per Cc. 1 cc and 1.5 cc ampuls and 10 cc rubber capped vial. A sterile aqueous solution of liver preserved with 0.5 per cent phenol.

BUFFINGTON'S, INC., WORCESTER, MASS

Purified Solution Liver, 10 U S P (Injectable) Units per Cc. 10 cc vial. A sterile aqueous purified solution of liver preserved with 0.5 per cent phenol.

FLINT, EATON & CO., DECATUR, ILL

Liver Injection (Crude) 1 and 2 U S P Units per Cc. 15 cc and 30 cc multiple dose vial. A sterile aqueous purified solution of liver preserved with 0.5 per cent phenol.

ALUMINUM HYDROXIDE GEL (See New and Nonofficial Remedies 1943 p 365)

The following additional dosage form has been accepted:

ALBA PHARMACEUTICAL DIVISION, WINTHROP CHEMICAL COMPANY, INC., NEW YORK, SUCCESSOR

Creamalin (Unflavored) Contains 5.5 per cent aluminum hydroxide (equivalent to 3.6 per cent aluminum oxide). Marketed in bottles of 6 fluidounces and 1 pint.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies 1943 p 403)

The following dosage forms have been accepted:

GEORGE A. BREON & COMPANY, INC., KANSAS CITY, MO
Caplets Diethylstilbestrol 0.2 0.5 and 1 mg

SATURDAY, SEPTEMBER 11, 1943

CLOSTRIDIUM WELCHII INFECTION OF THE UTERUS

Gas gangrene of the uterus is a rare disease. Toombs and Michelson¹ in 1928 were able to assemble records of only 45 cases. Falls² in 1933 reported 6 cases, and Lash³ in the same year reported 3. Marchetti⁴ in 1934 found 56 cases reported in the literature, to which he added 1 of his own. The largest individual series is probably that of Russell and Roach,⁵ who in 1937 reported 17 cases of their own. Clinically the post-abort and the puerperal groups may be differentiated. How does the infection occur? Is *Clostridium welchii* a normal inhabitant of the vaginal tract? Bysshe⁶ obtained 45 per cent of positive *Clostridium welchii* vaginal cultures from 547 routine examinations of pregnant and puerperal women. Of the patients with positive cultures, 20 per cent showed some puerperal morbidity and clinical evidence of at least endometritis. Falls found gas bacilli present in the vaginal tract of 861 per cent of all cases in three hospitals. The incidence of positive cultures among his gynecologic cases amounted to 33 per cent and of incomplete abortions to 29.41 per cent. Douglas and Rhees⁷ obtained 35 per cent of positive *Clostridium welchii* cultures following operative deliveries.

The presence of *Clostridium welchii* organisms in the vagina does not apparently determine a clinical infection. A necessary factor for the development of a severe infection is intervention sufficient to introduce

the *Clostridium welchii* bacilli into the uterus. Wrigley⁸ believes that a severe maternal infection results not only from intrauterine manipulations which introduce the infection into the uterus but also from damage to the maternal tissues with the child dead at the time of manipulation. This opinion was supported by Lash but was denied by Toombs and by Hill on the basis of their reports of fatal puerperal infection in which the mother was delivered of a living child. Without mechanical intervention of some kind, *Clostridium welchii* infections are rare. Strains resembling those which cause fulminating infection have been present in the vagina but not in the uterus without resultant infection. This is in keeping with the supposition that *Clostridium welchii* does not usually gain access to the uterine contents except through intervention.

Recent bacteriologic studies by Hildred Butler⁹ showed that the strains of *Clostridium welchii* are subject to great variation. She studied more than 600 strains of this organism with regard to growth characteristics, capsulation in broth cultures, production of alpha toxin, phagocytosis by human leukocytes and pathogenicity of washed cultures for guinea pigs. The severe generalized infections were caused by two distinct and recognizable variants, and the nature of the patients' symptoms was correlated with the characteristics of the strain. The severe clinical cases could be divided into two groups: (1) those characterized by jaundice, which was usually accompanied by hemoglobinemia and hemoglobinuria, and (2) those characterized by collapse without jaundice. For a control group Butler used strains of *Clostridium welchii* from abortifacient cases without symptoms of severe infection or without symptoms of infection due to this organism. She found that all the strains causing severe general infection were heavily capsulated, resistant to phagocytosis and productive of fatal infection in guinea pigs when washed cultures were used. The observation that a certain proportion of *Clostridium welchii* strains are capable of initiating a fatal infection in the guinea pig when the inoculum consists of organisms washed free of toxin that some strains are resistant to phagocytosis by human leukocytes and that this resistance is practically unaffected by the presence of antitoxin but is completely removed by the addition of antibacteriologic serum appropriate to the strain concerned suggests that some strains are highly invasive in addition to producing a potent exotoxin. The importance of the invasiveness of the infecting strain has not been sufficiently investigated, probably because of preoccupation with the toxemic aspect of these infections.

9 Butler, Hildred M. Further Bacteriologic Studies of *Clostridium Welchii* Infections Following Abortion, *J Obst & Gynec Brit Emp* 50: 105 (April) 1943.

Sadusk and Manahan¹⁰ report 2 cases of postoperative infection with *Clostridium welchii* with positive blood cultures in which the blood stream was rapidly sterilized by the use of sulfanilamide and the patients recovered. They have also demonstrated the bacteriostatic action of sulfanilamide on *Clostridium welchii* in vitro. Coralie Rendle-Short¹¹ reports 6 cases. Four of the patients were treated with anti-gas gangrene and sulapyridine and all 4 recovered. The other 2 were not so treated and died. Evaluation of the effectiveness of the sulfonamides in *Clostridium welchii* infection of the uterus will not be possible until more clinical observations checked by complete bacteriologic studies, become available.

CHRONIC GASTRITIS AND CANCER OF THE STOMACH

Konjetzny in 1913 working with freshly fixed, resected material suggested that carcinoma of the stomach develops on an inflammatory basis. He formulated his concept of "gastritis hyperplastica atrophicans" and concluded that the greater portion of gastric carcinomas (about 85 per cent) arose on the basis of chronic gastritis and that the latter constitutes a precancerous condition. Investigations of Orator including a study of 700 cases of ulcer and 150 of cancer, seemed to establish a close association between the presence of chronic gastritis and its allied intestinal metaplasia and that of gastric carcinoma. He concluded that about 80 per cent of gastric carcinomas arose on a basis of precancerous gastritis and that the remainder arose through cancerous transformation of gastric ulcers, so-called ulcerocancers. This opinion was supported by some workers in this field and was opposed by others. Some suggested that the gastritis was a result, rather than a cause, of the cancer.

Guiss and Stewart¹ working in the pathologic laboratories of the Memorial Hospital for the Treatment of Cancer and Allied Diseases made a careful anatomic study of the relationship of chronic atrophic gastritis and gastric cancer. For their study they used stomachs which were obtained immediately, or within two or three hours at most after death. Surgically resected material was obtained within five to ten minutes of its removal. Five distinct groups of material suitable for study were collected. Group A consisted of 35 stomachs obtained from premature infants born at from six months gestation to term and from a few infants who were stillborn at term or who died within a few days of birth. Group B was made up of 73 "normal" stomachs obtained from persons who had no history or other indication of gastric disease. With few exceptions

these were all from persons who died as a result of trauma or from acute infectious diseases of short duration. This group was augmented by an additional 22 specimens from young subjects who died of electric shock. Group C included 77 "normal" stomachs obtained from patients who died of nongastric cancers. None of these patients gave any history of gastric symptoms and as far as could be ascertained differed from group B only in that they died of cancer after prolonged illnesses. Group D was composed of 73 gastric carcinomas, the majority being surgically resected specimens. Group E was a miscellaneous group of unselected consecutive stomach specimens resected for gastric lesions other than carcinoma, such as gastric ulcer, myoma and sarcoma.

The microscopic studies showed that intestinal metaplasia, heterotopia of the pyloric glands, mucosal cysts, heavy leukocytic infiltration and large numbers of lymphoid aggregates were not found in truly normal stomachs but were evidences of gastric changes. Stomachs of patients who died of cancer other than gastric cancer were essentially identical with those of persons who died from other causes, except that they contained fewer lymphoid follicles and collections and less leukocytic infiltrate. This difference was directly proportional to the degree of malnutrition present and was not due to the presence of cancer itself in the patient. Eighty-two per cent of stomachs from apparently normal persons who died within the gastric cancer age (over 40) showed microscopic evidence of chronic atrophic gastritis. Sixty-six per cent of stomachs from persons over 40 who died of extragastric cancer showed microscopic evidence of chronic atrophic gastritis. Ninety-seven per cent of stomachs with gastric carcinoma showed associated chronic atrophic gastritis. There was a similar incidence of chronic atrophic gastritis in association with gastric diseases other than carcinoma.

The chronic atrophic gastritis associated with gastric carcinoma appears therefore, to be a nonspecific "reaction" to inflammation and gastric injury in general. The authors did not see any evidence to suggest an etiologic relationship except that chronic atrophic gastritis may be caused or intensified by the presence of carcinoma in the stomach. The factors included in the present concept of chronic atrophic gastritis, such as mucosal atrophy, increased amounts of leukocytic infiltrate and lymphoid aggregates, intestinal metaplasia and pyloric gland heterotopia are all rather closely correlated, variation in one factor tending to be associated with proportionate changes in the others. This correlation probably justifies the consideration of these changes as a pathologic entity.

Guiss and Stewart feel that the concept that chronic atrophic gastritis is a precancerous lesion is not borne out by their observations. They point out that the slight difference in incidence of gastric atrophy between

10 Sadusk, J. F. Jr. and Manahan, C. P. Sulfanilamide for Puerperal Infection Due to *Clostridium Welchii*. *J. A. M. A.* 113: 17 (July 1) 1939.

cancerous and noncancerous stomachs in their series is far from being convincing. Atrophic gastritis is an exceedingly common condition with advancing age. Mere statistical correlation of incidence of gastric atrophy and of gastric cancer is quite insufficient to show causal relation. Both atrophy and cancer appear to be events in aging organs. Gastric cancer is probably correlated not only with gastric atrophy but with atrophy of other organs, such as the genitalia, breasts, circulatory apparatus or even the skin, thus reducing to absurdity the conclusions based on mere statistics as to incidence.

Current Comment

DEHYDRATED NERVE GRAFTS

To avoid sacrificing a "minor" nerve for repair of a more vital one, numerous zoologists have tried grafts of preserved or fixed nerves, such as petrolatum stored grafts or grafts fixed in alcohol or solution of formaldehyde. None of these have proved satisfactory. Since these failures were presumably due to denaturation of the stored nerves, Weiss and his colleagues¹ of the department of zoology, University of Chicago, have developed a nondenaturing preservative method. Nerves dissected aseptically were dropped into isopentane which was immersed in liquid nitrogen at -195°C , where the nerves froze instantaneously. The frozen nerves were then dehydrated over phosphorus pentoxide in a high vacuum at -40°C and the resulting dried nerves were stored in sealed aseptic containers. Before using, the stored nerves were rehydrated usually by immersion in isotonic solution of three chlorides in vacuo at room temperature, where they resumed their normal appearance and major histologic characteristics, including specific staining reactions.² Thus far segments of these rehydrated "devitalized" nerves about 1 to 2 cm in length have been grafted into gaps in hindlimb nerves of 38 rats, 4 cats and 18 monkeys. The grafts were usually spliced to the severed nerve stumps by two short arterial sleeves.³ Twenty-one homoplastic (rat to rat) grafts and eight heteroplastic (cat to rat) grafts have been studied microscopically from six days to eighteen weeks after the operation. Homoplastic devitalized grafts heal and promote regeneration much as do live grafts. Sheath cells and nerve fibers invade the grafts promptly, traveling in straight parallel courses without appreciable branching or confusion. Four months after the operation, regeneration is so perfect that there is no evidence of the old proximal "suture line." The regenerated fibers are of normal caliber with normal impulse conduction, motility and sensitivity being fully restored. In contrast, heteroplastic devitalized grafts are unsuccessful, behaving much like foreign bodies. Weiss concludes from this evidence that frozen-dried homoplastic nerve grafts are of clinical promise and that "banks of assorted nerve sizes stored in the dry condition could readily fill a steady demand."

ORAL AND RECTAL TEMPERATURES AFTER EXERCISE

Temperatures taken by rectum are about 1 degree F higher than those taken by mouth. The body temperature rises several degrees as a result of exercise, the extent of rise being dependent on the amount, intensity and nature of the exertion. Recently Brennemann¹ reported the recording of the rectal and oral temperatures just before and just after various degrees of exercise in 10 children and 3 adults, all apparently in sound health. The rectal temperatures rose from 1 to 4 degrees F higher after exercise while oral temperatures remained relatively unchanged, rose only slightly or even dropped. The increase in rectal temperatures and hence the variation from the oral was directly proportional to the intensity of the exercise. Normal temperatures both by rectum and by mouth were resumed in from thirty to sixty minutes. The clinical implications are obvious: a high afternoon or postexercise rectal temperature in a child cannot be presumed to reflect a disease process and conversely the danger of such a high temperature masking a disease process should not be overlooked.

ALCOHOL AND IMMUNIZATION

During several cholera epidemics of the nineteenth century higher mortality rates were noted among excessive users of alcohol than among the nonalcoholic. From this Koch¹ concluded that alcoholic intoxication lowers natural resistance to the cholera vibrio, this conclusion was afterward extended to include other pathogenic micro-organisms.² Lushbaugh³ of the department of pathology of the University of Chicago has recently made tests to study the effects of alcohol on acquired specific immunity in laboratory animals. Active immunity against pneumococci was produced in rabbits by repeated subcutaneous, intra-abdominal and intravenous injection of a formaldehyde killed type I vaccine. After six injections of this vaccine the rabbits yielded serums which agglutinated homologous type I pneumococci in dilutions as high as 1:1,280 (average 1:640). An additional group of rabbits was immunized passively by intravenous injection of commercial immune rabbit serum given in amounts sufficient to raise their specific agglutinating titer to 1:80. Inoculation tests showed that both methods of immunization afforded adequate protection against 0.1 cc of a six to eight hour broth culture of living type I pneumococci given intracutaneously. The same dose caused 100 per cent fatalities in control nonimmunized rabbits. Alcohol was administered orally by means of a stomach tube to 34 actively immunized, 15 passively immunized and 22 nonimmunized rabbits. The usual dose was 50 to 60 cc of 24 per cent alcohol, an amount sufficient to produce a stuporous condition bordering on coma. This dose usually raised the alcohol content of the blood stream to 400 to 600 mg per hundred cubic cm.

timeters, which concentration was maintained by giving additional doses of alcohol as needed. Two hours after the intoxication was begun each rabbit together with a nonintoxicated control was given the routine test dose of pneumococci. Of 27 nonintoxicated immune controls only 1 rabbit died of pneumococcic septicemia, a 3.7 per cent mortality. Of 49 intoxicated immune rabbits 32 died, a 65 per cent mortality. Both active and passive immunity was therefore almost completely suppressed as a result of two hours of alcoholic intoxication. Differences were noted between the dermal lesions at the site of the test injection in the intoxicated and the nonintoxicated groups. In intoxicated animals the local edema and leukocytic infiltration were reduced, suggesting an almost total suppression of the local inflammatory reaction. Lushbaugh found that the alcoholic lessening of immunity can be partially overcome by a massive (fivefold) therapeutic dose of commercial antiserum. This confirms the current clinical belief that a "double dose" of antiserum is necessary in the alcoholic.

PROBLEMS OF PERSONNEL IN TUBERCULOSIS SANATORIUMS

The incidence of tuberculosis has risen throughout the warring nations. The unprecedented increase in discovery of early tuberculosis by mass roentgenography places new stress on facilities for the care of tuberculous patients in sanatoriums. The recent report¹ under the auspices of the Trudeau Society, of the personnel problems of tuberculosis sanatoriums resulting from war conditions is hence particularly timely. This report is based on detailed information obtained from two hundred and thirty-four institutions caring for nearly 40,000 patients. Large institutions have had a greater loss of personnel than smaller ones. Sanatoriums in the middle Atlantic and New England states have suffered most and hospitals in the Rocky Mountain states least. The loss of personnel has involved physicians, nurses, pharmacists, dietitians, social service workers, technicians and indeed all categories of personnel. In the face of this situation the council of the American Trudeau Society has adopted a resolution that measures be taken immediately to insure proper financial support for existing sanatoriums, that reduction in the number of available beds be not approved and that the situation be brought to the attention of the War Manpower Commission with the request that measures be taken to insure adequate personnel both in number and in quality so that tuberculosis sanatoriums can effectively carry out their part in the war effort. Hospitalization is the major factor in the control of tuberculosis in the patient as well as in the community. When existing sanatoriums cannot maintain adequate or usual capacity or acceptable standards of service at the same time as case finding surveys are discovering new cases of tuberculosis in large numbers, all the agencies concerned, social and governmental, must cooperate in well organized and resolute efforts to provide needed facilities.

¹ Personnel Problems of Sanatoria Resulting from War Conditions. Report of a Study Made by the Committee on Sanatorium Standards, American Trudeau Society. Medical Section of the National Tuberculosis Association, April 1943.

MOTOR VEHICLE ACCIDENT FATALITIES

Over twenty-five thousand deaths were reported as having occurred from motor vehicle accidents in 1941 in thirty-seven states, the District of Columbia and New York City.¹ These figures represent a motor vehicle accident rate of 30.7 per hundred thousand of population; they have recently been analyzed by the Bureau of the Census. The analysis reveals many factors related to the time, place and other features of the accident which should prove valuable to traffic safety engineers and educators. From the medical point of view it is important that 67.5 per cent of the death certificates for victims of fatal motor vehicle accidents specified the motor vehicle as the only cause of death. In these cases the average life after the occurrence of the accident was 1.4 days as contrasted with the duration of 8.4 days for fatalities from accidents which were complicated by other conditions. Such a list of complications includes diseases present before the accident or those which resulted from or were aggravated by the accident itself. The most frequent cause contributing to death was intracranial lesions of vascular origin (cerebral hemorrhage, embolism and thrombosis). Other disease of the circulatory system (hemorrhage outside the brain) was another frequently associated condition. When hemorrhage was the most important contributory cause of death the duration of injury was only 1.5 days. A large proportion of deaths that specified only one cause—motor vehicle accident—also appear to have resulted from hemorrhages, hence the importance of prompt first aid is readily apparent.

FALSE POSITIVE SYPHILITIC REACTIONS

False positive syphilitic reactions have been attributed to numerous causes, with smallpox vaccination recently added to this list. Using the Kolmer Kline, Hinton and Mazzini techniques, Lynch¹ found that pseudosyphilitic serum reactions developed in 16 per cent of his patients within two weeks after vaccination. The serums usually remained positive for at least two months. In order to confirm these data a group of 202 serologically negative medical students and nurses was vaccinated by Favorite² of Hahnemann Medical College followed by periodic serologic tests with the Kolmer, Kahn and Mazzini techniques. From fourteen to sixty days after vaccination, 24 (11.8 per cent) of these individuals gave positive pseudosyphilitic reactions with one or more of these techniques. Many of the reactions were of 3 or 4 plus intensity. Subsequent retests made at fourteen day intervals showed that the false positive syphilitic reactions gradually decreased in intensity. All serums became negative by the end of four months. The pseudoreactions were about equally divided between the nonimmune and the accelerated (vaccinoid) groups, none occurring after immune vaccination reactions.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

PLAN FOR THE ALLOCATION OF INTERNS AND RESIDENTS IN HOSPITALS, 1944

Approved by Directing Board, Procurement and Assignment Service

In view of changing needs, both civilian and military, and of the last year's experience in attempting an allocation of hospital house staffs, a new allocation plan has been developed. It involves three major changes. The first of these is that internships and residencies are being changed over from a twelve to a nine month base period to remedy the difficulties inherent in a nine month medical school year and a twelve month hospital year. The second is that certain essential commissioned men will be permitted to give some service as hospital residents, under conditions outlined here. The third is that interns as well as residents are included in the allocation plan. One of the reasons for this change is that hospitals which have shifted from two year to one year internships have drained by approximately 1,400 the supply of interns which would in earlier years have been available to smaller hospitals.

COMPLIANCE

This year certain hospitals have failed to cooperate with the Procurement and Assignment Service plan because of their reliance on Selective Service deferments for the maintenance of their staffs. Since Selective Service deferment of residents is rapidly becoming a thing of the past, hospitals will find it of great advantage to cooperate with the Surgeon Generals and the Procurement and Assignment Service in this new allocation plan, which is designed to provide an equitable distribution of the house staff members available.

SHIFT FROM TWELVE TO NINE MONTH BASE

There has been general dissatisfaction with the three month overlapping of intern and resident services, which have been wasteful of urgently needed medical manpower.

To remedy this situation the Directing Board of Procurement and Assignment Service proposed on the recommendation of its Hospital Committee that a nine-nine-nine month plan be adopted. For those men who would be commissioned the proposal was:

The internship should be reduced from twelve to nine months.

One half of the interns should be retained for a second nine months as assistant residents.

One half of that group should be retained for a third nine month period as residents.

AGREEMENT WITH SURGEON GENERALS

This proposal has been accepted by the Surgeon Generals of the Army and Navy in this modified form:

The internship shall be reduced to nine months.

One third of the interns who hold commissions in the Army and Navy may be deferred for nine months (tenth to eighteenth months).

One half of this number or one sixth of the total number of commissioned interns may be deferred for an additional nine months (nineteenth to twenty-seventh months).

Acceptance of the plan by the Surgeon Generals is conditional on agreement by the state boards of medical examiners that eligibility for licensure of those who receive only nine months' internship will not be impaired and with the understanding that internships shall begin within thirty days after the completion of the medical course and that hospitals will limit their appointments of interns and residents to individuals who hold commissions or who have been officially rejected for commissions in the armed forces.

DEFINITION

In the interest of uniformity under this program the Procurement and Assignment Service will classify house officers as follows: interns during the first nine months, assistant residents during the second nine months and residents during the third nine months of hospital service.

The Procurement and Assignment Service believes that minimum adequate hospital medical service can be provided only if each hospital exerts every effort to obtain and retain women and physically disqualified house officers, since the number of men to be deferred by the armed services will not be adequate to meet even the minimal needs for hospital residents, and since the Procurement and Assignment Service cannot assign men to house staff positions.

The overall cut will be about one third. For the average hospital the allocation for 1944 will be somewhat less than two thirds of the 1940 number of residents and two thirds to three fourths of the 1940 number of interns.¹ It will be necessary in general to make proportionate cuts from 1940 in the new house staff quotas with certain adjustments for present teaching loads and pronounced shifts in patient population. The number of house staffs included in the quotas of the individual hospitals will include women physicians and all male physicians whether or not physically disqualified and whether or not commissioned. The allocation of this personnel will be primarily on the basis of the needs for civilian medical care.

CHANGE OVER TO NINE MONTH PLAN

Under this plan two thirds of all commissioned interns now in hospitals will be eligible for orders to active duty on or about Jan. 1, 1944 (nine months after the beginning of their internships) and at about the time the new graduates will be beginning their internships.

In many hospitals there are residents holding commissions who have already been deferred by the Army or Navy until July 1, 1944.

On their departure certain house staffs will be reduced below the quota level for three months. For most hospitals this will come at a time of relatively low census. In cases of extreme difficulty every effort will be made by the Procurement and Assignment Service to assist the hospitals through this three month period.

PROCEDURES

All hospitals have been asked to submit immediately analyses of their present and past situations for the purpose of facilitating this allocation for 1944. Based on this information and on field studies now in progress, the Hospital Committee will complete its estimates of the total number of physicians.

¹ The 1940 figure for interns include all physician registrars interns by the educational number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION regardless of the length of their appointment.

who will be available for house staff positions in 1944. With this information the committee will set house staff quotas for each hospital and from them build state quotas. In setting tentative quotas by the Procurement and Assignment Service for individual hospitals consideration will be given to obvious injustices which might occur in a too arbitrary application of the allocation plan.

Each state will be required to remain within its total quota that is no requests will be granted for deferments which would bring a state total over the quota established for that state. The state chairman may find it desirable to make certain changes in hospital allotments within the limits of his total state quota. Such changes will be subject to appeal and review at the national level. State chairmen will receive requests for deferments from hospitals and transmit them to the Washington office of the Procurement and Assignment Service which will review them and make recommendations to the Surgeon General.

A commissioned intern may move to a second hospital at the end of his nine or eighteen month service, so a hospital may ask for the service of a commissioned intern or assistant resident from another hospital for a nine month assistant residency or residency. In other words, movements of physicians on house staff shall not be discontinued or discouraged as long as the physician desires the hospital service and the hospital and state remain within their quotas.

NOTE—The Council on Medical Education and Hospitals of the American Medical Association has approved the plan described. The shortening of the internship is a regrettable wartime necessity but certain undesirable features of the existing house staff program should be corrected by the plan.—Ed

WARTIME NURSING IS DIFFERENT

Statement Issued by Directing Board of War Manpower Commission's Procurement and Assignment Service for Physicians, Dentists, Veterinarians, Sanitary Engineers and Nurses

It is utterly impossible to provide the necessary volume of wartime nursing service on a peacetime basis. Places where nursing is going on as usual must share with others. Individual nurses who have not made adjustments to wartime needs for their service should understand the necessity for their participation.

The National Nursing Council has pointed out that the value of any national plan must be judged by its usefulness at the local level, i. e. where nurses live and work—in the country in the villages, towns and cities of the nation.

Wartime nursing is different! That inescapable fact must be generally accepted by nurses by physicians and by hospital administrators. Energy and motion now spent in resistance to change must be released for the attack on war created needs.

Nurses have wrought many changes, but not enough in the pattern of nursing service since Pearl Harbor. "We just do the best we can" is heard more frequently than "This is our plan." Generally speaking educational programs have received more thought than the service programs. Acceleration of the basic course in nursing is an outstanding example. State boards of nurse examiners have initiated others.

The principles of good nursing have not changed, but nurses are learning to concentrate on the essentials. In the analysis and administration of nursing service radical changes are being made. Tremendously valuable assistance in caring for patients is being secured from the Red Cross nurses aides and other volunteers as well as from paid auxiliary workers.

Thus far nursing has not been rationed; such rationing would be complicated by the differences in individual nurses and the degree of essentiality of needed services. The sharing of services is more difficult than the sharing of goods.

A critical shortage of nurses exists. Here are the facts.

Over 36,000 nurses are now with the armed forces and the Red Cross has accepted responsibility for the recruitment of an equal number by June 30, 1944. Our men are receiving skilled medical care of a high order, as shown by the high

percentage of recovery from injury. Skilled nursing is an important factor in such care. Then too the very presence of nurses near the bases of military operations has repeatedly been described as a potent force in maintaining morale.

There has been an unprecedented increase in the use of civilian hospitals. Hospitals gave fourteen and a quarter million more days of care in 1942 than in the preceding year, and the trend still is definitely upward. This is in keeping with the rapid growth of the Blue Cross (group hospitalization) plans and the Children's Bureau hospitalization program for the care of the families of service men.

Nursing is essential to the nation's health. The National Nursing Inventories (of nursing resources) of 1941 and 1943 by the U. S. Public Health Service offer a comparison of data for the two years.

The total number of nurses graduated in the two years is well in excess of the number withdrawn for military service; this fact is not apparent in the inventory. The returns are apparently incomplete. Active nurses who did not return their questionnaires apparently did not realize the profound importance of the information requested. This information is the basis for present planning and safeguarding the future.

The relatively small decrease in the number of institutional nurses is much less significant than the increased use of hospitals in creating the serious shortage of nurses.

The large number of inactive nurses who reported themselves available is encouraging but available for what? Full time? Part time? These nurses and others who are still 'hidden' can make a valuable contribution to our nursing resources. Although it requires a little more planning the service of two part time nurses can equal that of one full time nurse. Wartime nursing puts a tremendous burden on all the administrative nurses.

Here is the program of the new Nursing Division of the Procurement and Assignment Service. The Red Cross recruitment committees are pledged to recruit 36,000 nurses this year. The new division will (1) determine the availability for military service or essentiality for civilian service of all nurses eligible for military service and submit such determinations to the American Red Cross for use in procurement of nurses for the armed forces; (2) promote plans for maximum utilization of full time nurses and those who are able to serve only part time; (3) develop and maintain a roster of all graduate registered nurses; and (4) develop and encourage sound methods of supplementing the work of nurses with nonprofessional personnel.

National Nursing Inventories

	1941	1943
Total returns	289,286	259,174
Active		
Institutional	81,708	77,704
Public health	17,766	18,900
Industrial	5,512	11,220
Private duty	46,793	44,299
Other	21,276	18,476
Inactive but available for nursing	2,252	8,746
		(of the 23,576 are married and under 40)
Inactive not available	90,979	49,829
In Nurse Corps of Army and Navy	6,571	over 36,000
		(precise data not available)

Through the War Manpower Commission not only will nursing have the benefit of the experience of medicine in the procurement and assignment of physicians but means will be found to interpret wartime nursing to physicians and their cooperation secured in effecting desirable wartime adjustments.

PHYSICIANS NEEDED FOR COAST GUARD

A request for physicians who are needed immediately for service with the United States Coast Guard has been made by the War Manpower Commission's Procurement and Assignment Service.

In a communication addressed to the state chairmen for physicians of the Procurement and Assignment Service, the latter's directing board requests that the central office of Procurement and Assignment Service be supplied immediately with the names of a specified number of available physicians "who are not

physically disqualified so that representatives of the United States Public Health Service may get in touch with them with a view to inviting them to apply for commissions."

The United States Public Health Service furnishes the physician personnel for the Coast Guard. The request states that state chairmen should continue furnishing each month until further notice a specified number of names of available physicians for possible recruitment by the United States Public Health Service.

MISCELLANEOUS

EXTENSION OF TIME FOR FILING DECLARATION OF ESTIMATED TAX GRANTED ARMED FORCES

Any taxpayer who is a member of the military or naval forces of the United States in active service on September 15 has been granted an extension of time for such period as may be necessary but not beyond March 15, 1944, within which to file the declaration of estimated tax required by the Current Tax Payment Act of 1943 and to pay such estimated tax or any installment thereof otherwise required to be paid before March 15, 1944.

If under the terms of the extension the time for filing a declaration of estimated tax is extended beyond the close of the taxpayer's taxable year and the taxpayer makes his income tax return and pays the tax for such taxable year on or before March 15, 1944, no declaration of estimated tax need be filed for such year.

As used in the recent regulation authorizing the extension of time for the filing of declarations and paying tax, the term "member of the military or naval forces of the United States" includes any individual in the Army of the United States, the United States Navy, the Marine Corps, the Coast Guard, the Army Nurse Corps, Female, the Women's Army Corps, the Navy Nurse Corps, Female, the Women's Reserve Branch of the Naval Reserve, the Women's Reserve branch of the Coast Guard Reserve and the Women's Reserve branch of the Marine Corps Reserve (Marine Corps Women's Reserve) and any commissioned officer of the Coast and Geodetic Survey or of the Public Health Service.

THE U S CADET NURSE CORPS

Surg Gen Thomas Parran, U S Public Health Service, Miss Lucile Petry and Mrs Eugenia K Spalding, director and associate director respectively of the U S Cadet Nurse Corps, have completed a nationwide tour in response to a request from the National Nursing Council for War Service and the American Hospital Association to provide first hand information to hospitals and nursing schools about the new Nurse Corps. The tour began at Harrisburg on August 9 and ended at Seattle on September 1. Great interest has been shown in this new program, which will provide nursing education without cost to the student. This is not a federally standardized program, Dr Parran said, corps members will attend any of the thirteen hundred accredited nursing schools that meet requirements of the law. The quota for the corps is 65,000 new student nurses this year. They will receive monthly allowances of from \$15 to at least \$30, and during the final period of training maintenance and monthly allowances will be paid by the school of nursing or hospital.

ORDER RESTRICTING USE OF NUTGALLS AND TANNIC ACID REVOKED

The order restricting the use of nutgalls and tannic acid U S P was revoked on August 24 by the War Production Board. Order M-204 controlling the distribution of these products was put into effect on Aug 8, 1942 chiefly to conserve supplies of tannic acid for use in the treatment of burns.

The National Research Council has advised the War Production Board that medical opinion has been increasing pro-

gressively against the use of tannic acid in burn treatment and that the Committee on Surgery of its Division of Medical Sciences recently voted that the use of escharotics be discontinued.

A fairly generous supply of nutgalls is available for the manufacture of tannic acid U S P. This supply is supplemented by importations from Peru of tara, from which tannic acid is made. The WPB Chemicals Division considers that there no longer is a critical shortage in this field.

STATEMENT OF PROTEST OF NETHERLANDS PHYSICIANS

The Office of War Information received on August 10 reports from overseas sources concerning the struggle by 6,200 physicians in occupied Holland to avoid compulsory membership in a Nazi controlled medical association. According to the reports, the Dutch physicians in June voluntarily renounced the practice of their profession rather than join the Nazi dominated Chamber of Physicians. The physicians sent a protest statement to Arthur Seyss-Inquart, reich commissioner for the Netherlands, explaining their refusal to join. Several hundred physicians were arrested following receipt of the statement, but most of them were released after several weeks during which medical service in Holland was brought to a virtual standstill. Nazi authorities agreed to permit the doctors to return to practice if they would sign a statement that they had not intended their protest as an "insult" to the occupation authorities or as a "political" gesture. The physicians agreed. Shortly after this truce, however, Seyss-Inquart ordered a fine to be imposed on the doctors of Amsterdam.

The text, slightly edited, of the statement to Seyss-Inquart, in which Dutch physicians explained their refusal to join the Nazi controlled Chamber of Physicians, follows:

"It was with astonishment and indignation that we doctors of the Netherlands learned of your latest instruction concerning the practice of our profession.

"This instruction stipulates among other things that doctors are no longer at liberty to give up their profession or renounce the title connected with it.

"This means that you are again trying to force them to join the Artsenkamer. You threaten with severe penalties those who act contrary to your instructions.

"It has been the practice of Netherlands doctors to work in the interests of our patients and our people. Medical care and sanitary conditions in the Netherlands have always been on a high level, thanks to the quality of our research and practice. The Netherlands Society for the Promotion of Medical Science has maintained high standards as a professional organization. It worked along Dutch rules, built on Dutch traditions, and included almost all Netherlands doctors. We have voluntarily abandoned this excellent organization because we wanted to prevent the enslavement of the Dutch medical body. You then founded the Artsenkamer, which was to impose on us national socialist principles.

"Mr Reich Commissioner, you must have realized with what aversion we looked on this imported institution imposed on us. The doctors of the Netherlands had and have a great distrust of this organization. In December 1941, on behalf of 4,501

doctors a letter was addressed to you in which you were urgently requested not to take the steps to apply national socialist measures in the field of medicine. The implementation of racial theories resulting in the deportation of the insane and sick persons and the sterilization of healthy people proves that much of our anxiety was justified. Proof of how much this association runs counter to the spirit and inclination of the Dutch doctors is furnished by the fact that recently 6200 of them voluntarily ceased practicing in order to escape your medical association.

Nevertheless, you are trying through coercive measures to impose on us what we do not want and place us under the trusteeship of a small political group which does not have our confidence or respect.

Mr. Reich Commissioner, the doctors come under your latest decree because at the beginning of their career they took an oath. This oath binds us to certain ethical standards which make it impossible in the future to meet your demands. If it comes to a point where we are confronted with unacceptable demands, it might happen that without regard for your threats we would have to risk our freedom and lives.

"We expect that you will spare us this conflict and will let us work in freedom and peace. The further course of things will depend on you, and you, Mr. Reich Commissioner, are responsible for that to the Dutch nation."

WARTIME GRADUATE MEDICAL MEETINGS

In a preliminary report the Central Committee of the Wartime Graduate Medical Meetings announces that it presented some of the facilities at its disposal at the Georgia State Medical Association meeting which was held on May 13, 1943, at which Drs. James Means, Virgil P. Sidenstricker and William N. Evans appeared at the invitation of the committee.

Also on May 3-5 Drs. Edwin E. Osgood and L. T. Coggeshall participated in a refresher course at the invitation of the Wartime Graduate Medical Meetings offered by the University of Alberta Hospital in Edmonton, Alta.

The Regional Committees to date have responded as follows:

Region 1 (Maine, New Hampshire, Vermont and Massachusetts) and Region 2 (Connecticut and Rhode Island) have consolidated their activities and will work in cooperation with the First Service Command and the Naval District in the New England states. Plans are nearing completion for postgraduate courses at the Newport Naval Hospital for September 14-15-16, including a one day presentation of medical subjects, one day of surgical subjects and one day of subjects in the various fields of medicine. Approximately twenty-five speakers will be presented.

Plans are likewise being formulated for a one, two or three day program to be presented at New London in October.

In Region 3 (New York) courses have already been conducted and others are now being formulated. On July 23 a program covering the 'Diagnosis and Treatment of Cardiac Pain' was presented at the St. Albans Naval Hospital, on July 27 a two hour lecture on Chemotherapy was presented at the St. Albans Naval Hospital and on August 3 a lecture by Dr. Henry Meleny on 'Malaria' at the Brooklyn Naval Hospital. Plans are being made for lectures on shock, burns and plasma and the dysenteries for some time in September.

In Region 10 (Kentucky and Tennessee) the committee has planned an excellent course for the week of October 3 covering burns, shock, blood derivatives and substitutes, chemotherapy, general surgery and the dysenteries.

In Region 18 (Montana and Wyoming) plans are proceeding for courses to be offered in the autumn covering the subjects of anesthesiology, shock, burns, blood derivatives, clinical psychiatry, psychosomatic medicine, cardiovascular problems, dysenteries, acute respiratory disease, physical therapy, diagnostic roentgenology.

In Region 19 (Colorado and Utah) plans have been made for programs to be offered on September 30 and October 1 in Denver.

The national consultants are now compiling the names of prominent men throughout the entire country who are willing to serve on a national faculty. This faculty will aid the committees in meeting the demands for teachers.

Requests have recently been received in the central office for speakers to appear on the program being offered by the Dalhousie University for Medical Officers in the Canadian Forces during the week of October 11 and also for the annual meeting of the Saskatchewan Medical Society to be held in Regina, Sask., on September 16, 17 and 18.

PUBLIC HEALTH UNDER HITLER

According to *Donauzeitung*, Belgrade, June 20, on June 17 there were 20 cases of food poisoning in Athens, causing two deaths. Fresh measures are being taken by the police.

LBK announces in *Der Neue Tag*, Prague, on June 6 that all pharmacists with or without diplomas, who are not yet registered with the working community of the medical profession (*heilberufe*) in Bohemia and Moravia must register by June 15, 1943. This applies in the first place to all those not active in public pharmacies, i.e., those active in wholesale business, industry, offices (*behorden*), domestic service (*haushalt*) and so on. Only those pharmacists who comply with the order of registration in good time may expect that their qualifications will be considered in case of their mobilization for the war effort. The registrations are to be addressed to the 'Working Community of the Medical Profession in Bohemia and Moravia, Working Committee of Apothecaries, Prague II.'

According to *Glas Crnogorica*, Cetinje, March 31, the epidemic of smallpox among the Moslem refugees in the Plyeljje has been spreading. There are now 200 cases at least. Every day there are deaths.

According to Radio Rennes, July 12, an important delegation of French doctors went to Germany in July at the invitation of the general commissioner for foreign workers in Germany to attend special lectures in Berlin and then to be attached to different camps to supervise the health of their compatriots.

The dean of Marseilles University announced that the pharmacy medical students of the 1942 class are requested to carry on their professional activity in Germany for the benefit of the French workers. *Le Mot d'Ordre*, July 7, reports. The students will take care of those wounded in labor accidents and those suffering from illness or wounds resulting from the war. They will principally have to fight venereal diseases. The students had to pass a special examination in Paris on July 24 before being included in the medical personnel.

Vocea Romaniei, of July 7 stated that the cabinet has decreed that the Ministry of Social Policy and Health is authorized to summon for compulsory work all doctors, assistants, nurses, laboratory assistants, disinfectors and sanitary personnel irrespective of sex or whether they are publicly or privately employed. Those over 70 are exempted and those above 60 and mothers with children under 18 are employable only in their place of residence. Aliens may not be summoned.

According to Radio Romania, July 12, the minister of health has decided that universities must admit an extra number of medical students who are obliged to attend summer courses in hospitals in order to increase the number of doctors. Students will follow summer courses in the town or country hospitals and will be supervised by doctors. All students from the first to the third year will follow summer classes. For women students there will be two months practice and one month's holiday and for men one month's practice and one month's holiday.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Tests to Determine Intelligence of Spastic Children—

An initial endowment of \$5,000 has been given to the University of Southern California, Los Angeles, by the Crippled Children's Society of Los Angeles County and the California State Society for Crippled Children to undertake scientific research to develop tests for measuring the intellectual and performance capacities of spastic children. This particular phase of the study is being undertaken for the first time and will be supported over a period of five years. Volunteer public and professional organizations, as well as individuals dealing with spastic children, will have access to the psychometric clinic which is a unit of the psychology department at the University of Southern California.

Labor Unions Endorse Blood Test—The executive board of the California State Federation of Labor at its meeting held in Los Angeles June 12, recommended that member unions require each applicant for membership to have a blood test made before admission into the union. The results of such tests are to be a matter of strict confidence between the examining physician and the applicant. The results, under no circumstances are to be revealed to the union or to the employer and will have no bearing on the applicant's admission into the union. So far as is known this is the first time that union labor has taken this sort of action anywhere in the United States, according to *California's Health*.

Anesthetists Needed—Anesthetists are being sought by the Los Angeles County Civil Service Commission for positions in the Los Angeles County Department of Charities to render professional medical services in the care and treatment of patients in anesthesia services. Men or women who have graduated with a degree of M.D. from an approved medical school and who have completed at least a one year internship in an approved hospital are wanted for these positions. There are no maximum age limits nor residential requirements. Full information can be obtained from the office of the commission, Room 102, Hall of Records, Los Angeles 12. Applications must be filed on or before September 18.

CONNECTICUT

Clinical Congress—The annual clinical congress of the Connecticut State Medical Society will be held at the New Haven Medical Association, New Haven, September 28-29. Among the speakers will be

Dr. Alexander W. Winkler, New Haven, Insulin Derivatives and Their Combined Use
Dr. Cyril N. H. Long, New Haven, Recent Progress in the Problem of Shock
Dr. Edward L. Howes, Washington, D. C., Debridement, Not Chemo-therapy, Heals Wounds
Dr. Robert M. Lewis, New Haven, Caudal Anesthesia
Dr. Robert C. Batterman, Brooklyn, Demerol, a New Synthetic Analgesic: Its Indications as a Substitute for Morphine
Comdr. Francis J. Braceland (MC), U. S. Naval Reserve, Fatigue and Anxiety
Dr. Nolan D. C. Lewis, New York, Electric Shock Therapy in Psychoses—Indications and Present Status
Dr. Harry Gold, New York, Newer Digitalis Crystalline Compounds
Dr. Paul L. Boissert, New Haven, Tetanus Toxoid for the Civilian Population
Dr. Bernard S. Brody, New Haven, Osteomyelitis of the Skull
Dr. James A. Evans, Boston, Problems of Thrombophlebitis and Pulmonary Embolism
Francis H. L. Taylor, Ph.D. Boston, The Problem of Nutrition in the Presence of Excessive Nitrogen Requirement in Severely Ill Patients
Lieut. Col. Francis R. Dieuaide, M. C. A. U. S., Malaria

One session will be devoted to a discussion of modern knowledge of pulmonary disease with the following speakers: Drs. Francis G. Blake, New Haven, on "Acute Infections of the Lung"; H. McLeod Riggins, New York, "Some Difficulties in the Differential Diagnosis of Certain Pulmonary Diseases"; Kirby S. Howlett Jr., Shelton, "Recent Trends in the Therapy of Pulmonary Tuberculosis"; Leonard Greenburg, New York, "Industrial Pulmonary Problems," and Gustaf E. Lindskog, New Haven, "New Trends and Results in Surgical Therapy of Lung Suppuration." A series of demonstrations by members of the staff of Yale University Medical School is also planned.

GEORGIA

Annual Registration of Licentiate of State Examining Boards—On September 1 the Joint Secretary, State Examining Boards, started mailing to all licentiate of the State Board of Medical Examiners and of other Georgia state examining boards blanks to enable them to comply with the law requiring annual registration. No fees attach to such registration. Physicians will do well to execute the blanks furnished and to return them to the Joint Secretary as promptly as possible.

ILLINOIS

Personal—Dr. Joseph H. Chivers, medical director of Crane Company, Chicago, has been appointed chairman of the advisory committee to the state division of industrial hygiene, succeeding the late Dr. Philip H. Kreuscher. Dr. Frederick W. Slobe, Chicago, a new member of the committee, was named vice chairman.

Chicago

Fremont Chandler Named Professor of Orthopedic Surgery—Dr. Fremont A. Chandler, associate professor of orthopedic surgery at Northwestern University Medical School, has been appointed professor of orthopedic surgery and head of the department at the University of Illinois College of Medicine. Dr. Chandler will also be director of the Illinois Surgical Institute for Children. He succeeds Dr. Henry B. Thomas, who is retiring at the university after an affiliation since 1909. Dr. Thomas was instrumental in establishing the surgical institute for children which opened for patients in May 1931.

Eye and Ear Infirmary Now Directed by Welfare Department and Illinois University—The physical plant of the Illinois Eye and Ear Infirmary will be under the supervision of the state department of public welfare and all professional activities and all personnel connected with professional activities will be under the direction of the University of Illinois College of Medicine in accordance with an agreement recently announced by the university. Despite their appointments to Illinois, the members of the infirmary staff will retain their positions in other universities as well, and students of other Chicago universities will be given the clinical facilities of the infirmary as in the past. Dr. Harry S. Gradle, chief of staff of the Illinois Eye and Ear Infirmary, under the new setup becomes professor of ophthalmology at the medical school. Dr. Peter C. Kronfeld, dean of instruction at the infirmary, will become associate professor of ophthalmology at the medical school and director of education in ophthalmology.

INDIANA

State Medical Meeting—The ninety-fourth annual session of the Indiana State Medical Association will be held in conjunction with the Ninth Naval District at the Claypool Hotel, Indianapolis, September 28-30, under the presidency of Dr. Carl H. McCaskey, Indianapolis. Out of state speakers will include

Senior Surgeon Herman E. Hilleboe, medical officer in charge of Tuberculosis Control Section, U. S. Public Health Service, Tuberculosis Control in Industry
Admiral Ross T. McIntire, surgeon general, U. S. Navy, Navy Medical Services in Combat
Dr. Reed M. Nesbit, Ann Arbor, The Modern Treatment of Prostatic Cancer—A Rational Basis for Delayed Hormone Therapy
Dr. Norman H. Jolliffe, New York, The Cause, Signs and Treatment of Malnutrition
Comdr. John F. Lutten (MC), U. S. Navy, Battle Casualties with Special Reference to the Use of Sulfonamides
Dr. Ernest Perry McCullagh, Cleveland, The Use of Gonadal Hormones in General Medical Practice
Brig. Gen. George F. Lull, M. C., U. S. Army, The American Doctor in the War
Capt. Joseph A. Tartre, senior dental officer, Ninth Naval District, Navy Dental Corps at the Great Lakes Naval Training Station
Col. Thomas T. Mackie, M. C., U. S. Army, Tropical Diseases—A War and Postwar Problem Affecting the Continental United States
Dr. John M. Waugh, Rochester, Minn., Vaginal Hysterectomy: Indications and a Method
Dr. Peter C. Kronfeld, Chicago, Indications for Paracentesis of the Anterior Chamber
Dr. George J. Thomas, Pittsburgh, Pentothal Sodium, Range of Usefulness, Complications and Their Management

Dr. Harry S. Gradle, Chicago, will address the breakfast meeting, September 29, and Rear Admiral John Downes, Commandant, Ninth Naval District, will speak in the afternoon. The annual banquet will be held Wednesday evening with Dr. Herman L. Kretschmer, Chicago President-Elect of the American Medical Association, speaking on "War Problems Faced by the Medical Profession." A new feature of the program this year will be sixteen instructional courses to be held Tuesday at the Claypool Hotel. Each course will accommodate twenty members. Included among the subjects will be the treatment of pneumonia, recognition and treatment of

common skin diseases routine interpartum examination and care undulant fever tularemia Rocky Mountain spotted fever, recognition and treatment of early tuberculosis and neuro-psychiatric aspects of every patient

MARYLAND

Hospital News—The resident staff of Mercy Hospital, Baltimore recently inaugurated a program of weekly meetings. On July 16 Dr Henry F Zingari spoke on 'The Rh Factor and Its Relationship to Erythroblastosis Fetalis' and Dr John C Osborne on Tetrathionate. A new program of medical motion pictures has also been launched at the hospital. A film on Inguinal Hernioplasty sponsored by the Singer Sewing Machine Company, was shown on July 12.

Friedenwald Award Goes to Thomas Brown—The American Gastroenterological Association has awarded its 1943 Julius Friedenwald Medal to Dr Thomas R Brown, associate professor emeritus of medicine Johns Hopkins University School of Medicine Baltimore. Coincidentally the July issue of *Gastroenterology* was dedicated to Dr Brown in recognition of his many accomplishments as a clinician and a teacher and to mark his contributions in the field of gastroenterology. Dr Brown graduated at Johns Hopkins in 1897.

MASSACHUSETTS

Tufts Observes Fiftieth Anniversary—The Tufts College Medical School Boston, will celebrate its fiftieth anniversary with a number of exercises September 15 October 6. Included on the program will be a talk at the medical school September 15, by Major Gen James C Magee on Military Medicine with Special Reference to Tropical Diseases, a lecture before the William Harvey Society September 16, at the Beth Israel Hospital by Dr Timothy Leary professor emeritus of pathology at the school on 'Excess Cholesterol as a Pathogenic Agent' and a talk September 29 by Col Raymond W Bliss. On September 22 a feature of the celebration will be the presentation and unveiling of portraits of Dr Leary and Dr Cadis Phipps, professor of medicine. The anniversary exercises will conclude on October 6 with a general meeting at the John Hancock Hall at which the speakers will include Leonard Carmichael, LL.D., president of Tufts College and Capt A Warren Stearns (MC) USNR, dean of the medical school now on military leave. Another feature of the celebration will be the release of a book on the history of Tufts College Medical School written by Dr Benjamin Spector professor of anatomy and professor of the history of medicine which is said to be the first published history of the school.

MISSOURI

Physician Marks Ninety-Second Birthday—A reception was held at the Lucerne Hotel on August 25 to celebrate the ninety-second birthday of Dr Caleb Anderson Ritter, Kansas City. Dr Ritter graduated at the Indiana Medical College, Indianapolis in 1877. He is an Affiliate Fellow of the American Medical Association.

Starkloff's Name Added to St Louis Hospital—The St Louis City Hospital (The Max C Starkloff Memorial) is the new designation of the hospital in accordance with action taken recently to honor the first health commissioner of St. Louis who served thirty years under five mayors. A bill was recently adopted changing the name to Max C Starkloff Hospital but through the efforts of the medical staff, this action was repealed and the compromise name adopted.

Physicians Resign Because of New Full Time Health Policy—Dr James L Mudd since 1935 tuberculosis controller of St Louis and Dr Hyman I Spector chief of the medical dental and nursing section of the St Louis Health Department have resigned effective September 1. The resignations were the result of the new full time policy for physicians serving in executive capacities. The policy was recommended by the civil service commission and passed by the board of aldermen.

NEBRASKA

Annual Registration Due On or Before October 1—Physicians licensed to practice medicine in Nebraska are required by law to register with the Department of Public Welfare annually on or before October 1 and to pay a fee of \$1. A license expires if the licensee fails to register but within the thirty days next following its expiration it may be revived by the payment of the registration fee and a penalty of \$1. If that is not done an order of revocation is issued and thereafter the revoked license can be reinstated only on the recommendation of the board of examiners in medicine and on the payment of the renewal fees and penalties then due.

NEW JERSEY

Personal—Dr George W Tyrrell was guest of honor at a banquet on July 29 given by the medical profession of Perth Amboy and vicinity in honor of his completion of fifty years in the practice of medicine. Dr Tyrrell has been a member of the staff of the Perth Amboy General Hospital from its inception and was dean from 1927 to 1935.

Officers of State Medical Agencies—Dr John H Rowland New Brunswick was elected president of the New Jersey State Board of Medical Examiners on July 14 to succeed Dr Samuel Barbash Atlantic City. Newspapers report that he is the first New Brunswick physician to head the board. Dr Earl S Hallinger Camden was reelected secretary. Dr James Willory Carlisle Westfield was elected president of the state board of health at a meeting on July 13.

Dr Bristol Declines State Health Appointment—Dr Leverett D Bristol Montclair health director of the American Telephone and Telegraph Company has declined the position of state director of health to which he was recently elected (*THE JOURNAL*, July 31 p 959). The *New York Times* reported on August 18. In a statement to the press Governor Charles Edison said Dr Bristol's reasons for declining the position were set forth in a letter marked personal and confidential and that he was not free to reveal them.

NEW YORK

Grant to Install Blood Bank—A grant has been awarded by the government Office of Civilian Defense to the Arnot-Ogden Memorial Hospital in Elmira for the installation of a blood and plasma bank. The bank is one of many scattered within the 300 mile limit along the eastern coast for the purpose of maintaining an adequate supply of frozen plasma for possible civilian disasters and accidents in war factories.

Dr Bigelow Named Assistant Commissioner of Mental Hygiene—Dr Newton J T Bigelow Brentwood clinical director of the Utica State Hospital Utica has been appointed superintendent of the Hudson River State Hospital Poughkeepsie, and acting assistant state commissioner of mental hygiene. Dr Bigelow will fill the military absence of the present assistant commissioner, Dr Harry Beckett Lang Albany.

Building for Manufacture of Plasmochin—The Winthrop Chemical Company at Rensselaer is constructing a \$75 000 building to be devoted exclusively to the production of plasmochin. Completion of the building is expected by September 15 but operation will not start until about November 15. The new facilities are expected to increase the company's plasmochin production capacity about 300 per cent. The new building is located on the company's 27 acre plant property. One story high, the new unit is one of twenty-six manufacturing laboratory and office buildings operated by Winthrop in Rensselaer. For the production of penicillin a building outside the factory grounds has been leased.

Postgraduate Lectures—Two lectures on hypertension will be delivered before the Onondaga County Medical Society and the Syracuse Academy of Medicine in Syracuse October 19 under the auspices of the state medical society and the state department of health. Dr Herman O Mosenthal, clinical professor of medicine New York Post-Graduate Medical School and Hospital Columbia University will discuss the classification and medical treatment of hypertension and Dr J William Hinton associate clinical professor of surgery at the school the surgical treatment of hypertension. A lecture has been planned under the same auspices for the Delaware County Medical Society in Hamden September 14. Dr Roscoe D Severance Syracuse speaking on Pain In and Related to Adult Feet.

New York City

Rapid Treatment Center at Bellevue—The Federal Works Agency has approved a grant of \$290 000 to reconstruct one of the dormitory buildings at Bellevue Hospital for a rapid treatment center for venereal diseases and another grant of \$272 718 for maintenance. A convalescent rehabilitation camp on Welfare Island is also included in the project.

Ledyard Fellowship—The Society of the New York Hospital announces that applications for the Lewis Cass Ledyard Jr Fellowship must be received by the committee by December 15 for the 1944-1945 award. The fellowship was established in 1939 by Mrs Ruth E Ledyard in memory of her late husband a governor of the New York Hospital. The income amounting to about \$4 000 annually will be awarded to an

investigator in the fields of medicine and surgery or in any closely related field. About \$3000 will be available as a stipend and approximately \$1,000 for supplies or expenses of the research. In making the award, preference will be given to younger applicants who are graduates in medicine and who have demonstrated fitness to carry on original research of high order. Application for the fellowship should be addressed to the Committee of the Lewis Cass Levard Jr. Fellowship, the Society of the New York Hospital, 525 East 68th Street.

Program to Rehabilitate Men Discharged for Mental Illness—The New York Hospital has established a psychiatric rehabilitation program to aid in reclamation of men rejected or discharged by the armed forces because of mental illness. According to the *New York Times*, the private psychiatric project is said to be the first of its kind to operate in the metropolitan area. The Payne Whitney Psychiatric Clinic at the hospital has been conducting a special outpatient clinic since August 19 in cooperation with state selective service officials and social service agencies. Integration of psychiatric treatment with psychologic testing, retraining and employment is to be emphasized. The originators of the plan were Dr. Thomas A. C. Rennie, attending psychiatrist at the clinic and associate professor of psychiatry at Cornell University Medical College, who will direct the program, and Mrs. Kelly Simon, chief of psychiatric social service at the clinic. Dr. Rennie recently was named director of the division of rehabilitation of the National Committee on Mental Hygiene. The Commonwealth Fund has granted funds for the project. The clinic will serve as an actual treatment center for men in need of total overall service in their own rehabilitation and as a fact finding agency to determine the extent of the problem, the amount of help necessary for rehabilitation, the nature of psychiatric disabilities and what percentage of the patients treated may eventually be reemployed. It is expected that such facts may ultimately be of value in orienting federal authorities in their war and postwar rehabilitation planning. The social service agencies that will cooperate include the New York City Committee on Mental Hygiene, the Social Security Board, the United States Employment Service, the Vocational Adjustment Bureau, the American Rehabilitation Committee, the Community Service Society and the Young Men's Christian Association. The State Selective Service Board will refer cases to the clinic.

OREGON

Society Publishes Service Bulletin—The Oregon State Medical Society has started the publication of a *Service Bulletin* to meet the growing need for a medium of exchange of news and information and, especially, of mailing addresses. The state society believes that, with a third of its men in service, the need has outgrown the capacity of its office to care for it. According to the *Service Bulletin*, the journal *Northwest Medicine* has done its excellent best to fill the need, but, with three states to serve, it has neither the staff nor the space to cover these things in detail and still maintain its standard of scientific publication. The *Service Bulletin* will go to both physicians at home and in the field and to members of the society and to nonmembers. The bulletin was launched with the August issue and contains a roster of Oregon physicians in service with the most recent ranks and addresses that could be obtained. Needed information is indicated with an asterisk. In addition the bulletin contains news notes of medical activities of physicians in the state.

PENNSYLVANIA

Personal—Dr. Loyal A. Shoudy, chief of medical service, Bethlehem Steel Company, Bethlehem, was recently presented with the title "Alumnus Summa Laude Dignatus" as a part of the commencement exercises of the University of Washington, Seattle, and represents the university's annual election to honor an alumnus. Dr. Shoudy graduated at Washington in 1904. —A portrait of Dr. Thomas H. A. Stites was recently placed in the reception room of the surgery building at the Pennsylvania State Tuberculosis Sanatorium number 2 at Cresson to mark his recent retirement as medical director after serving for sixteen years (*THE JOURNAL*, May 29, p. 323). Dr. Stites has returned to his home in Nazareth and Dr. Benjamin Franklin Royer, Chambersburg, is acting medical director of the sanatorium.

Philadelphia

Report on Medical Art—Dr. Samuel B. Sturgis, honorary director, department of medical art, College of Physicians of Philadelphia, recently made available his first report. The department was launched in 1940 following the gift by Dr. Sturgis of a collection of medical art. At that time Dr. Sturgis

was asked to become honorary director or curator of the collection of medical art. The collection has now almost 7,000 items, covering prints, photographs and original documents, the subjects including buildings, certificates of membership, meeting notices, portraits, clinics, lectures, matriculation cards, medical celebrations, sculpture, medals and caricatures. The assembling of the collection was donated to the college by Dr. Sturgis. According to the first report, there are at least 200 more photographs and miscellaneous items to be incorporated. Eventually it is hoped to attend to such phases as medical drawings and illustrations. Among the contributors to the department of medical art have been Drs. William W. Keen, Astley P. C. Ashurst, George E. de Schweinitz, Albert P. Brubaker, James M. Anders, all of whom are deceased, and Drs. William N. Bradley, Francis R. Packard, Edward B. Krumbhaar, Burton Chance, Samuel McC. Hamill, and Mrs. J. Hampton Carson and Mrs. Erwin F. Faber. The original collection, containing twelve completed portfolios of the Faber collection donated by Dr. Sturgis, is named the Sturgis Collection of Medical Art of the Colleges of Physicians of Philadelphia.

RHODE ISLAND

Clifford Beers Dies—Clifford Whittingham Beers, founder and secretary of the American Foundation for Mental Hygiene, died on July 9 in Butler Hospital, Providence, after a long illness. He was 67 years old. Mr. Beers was born in New Haven, Conn., in 1876. He graduated at the Sheffield Scientific School, New Haven, in 1897. In 1908 Mr. Beers founded the Connecticut Society for Mental Hygiene, the first organization of its kind in the country. The following year he was instrumental in establishing a National Committee for Mental Hygiene, of which he served as secretary for a number of years. In 1928 he founded the American Foundation for Mental Hygiene, serving as its secretary. He organized and became secretary-general of the first International Congress on Mental Hygiene in Washington in 1930, establishing the same year the International Committee for Mental Hygiene. The following year he established the International Foundation for Mental Hygiene, also serving as its secretary. Mr. Beers was a member of many nationally known societies concerned with mental hygiene. He had received numerous awards for his work, including the Cross of Chevalier of the Legion of Honor by the French government in recognition of international work in mental hygiene and in 1933 the gold medal of the National Institute of Social Sciences for "distinguished services for the benefit of mankind." He was honored in 1934 by the publication of a presentation edition of "Twenty-Five Years After—Sidelights on the Mental Hygiene Movement and Its Founder," containing about five hundred twenty-fifth anniversary tributes, collected by the late Dr. William H. Welch, chairman of the Tribute Committee, appointed by the National Committee for Mental Hygiene in connection with the anniversary celebration. The author of numerous articles on mental hygiene, Mr. Beers outlined his early experiences in his autobiography "A Mind that Found Itself" first published in 1908. According to the *New York Times*, in 1900, overpowered by a delusion that he was doomed to a serious disease, he leaped from a fourth story window but suffered only a few broken bones in his feet. The suicide attempt, however, caused him to regard himself as a criminal, hunted by detectives. His family placed him in a private sanatorium, where he lived for two years, never speaking. In another institution he began to grope his way out of the darkness. He then conceived the idea of reforming insane asylums, and, to gather material for his crusade, actually fought his way into the violent wards of both a private and a state institution. He spent some three hundred hours in a strait jacket and was also committed to a padded cell. Eventually he got a letter through to the governor of Connecticut, and some of the more brutal attendants were discharged. Mr. Beers was finally released as cured in 1903. He returned to business in 1904 but in 1906 gave it up, resolved to devote his life to improving the condition of the insane and to aiding the mentally ill. He wrote and published his book in 1908.

TEXAS

Houston Post Publishes Baylor Section—On July 31 the *Houston Post* published a supplement devoted exclusively to the Baylor University College of Medicine, Houston. The issue contained photographs, feature articles, lists of faculty appointments and general discussions of the activities of the school, which recently moved from Dallas to Houston.

GENERAL

Society for Research in Psychosomatic Problems—Information has just been received concerning the first annual meeting of the American Society for Research in Psychosomatic Problems held in Detroit in May at which Dr Winfred Overholser Washington D C, was named president-elect Dr Tracy I Putnam New York president and Dr Edwin G Zabriske, New York secretary-treasurer Dr Adolf Meyer, professor emeritus of psychiatry Johns Hopkins University School of Medicine Baltimore was chosen honorary president The constitution was unanimously adopted and research committees on psychosomatic problems in obstetrics and gynecology early infancy and childhood physiologic mechanisms and the psychosomatic implications of animal experimentation psychosomatic teaching in medical schools psychosomatic research in psychosomatic problems, psychosomatic approach to social and cultural problems and psychosomatic problems in war medicine internal medicine and industrial medicine The meeting was held in conjunction with the meeting of the American Psychiatric Association The society was created last year but the formal organization was delayed until the joint meeting with the American Psychiatric Association in Detroit

Academy of Neurological Surgery—The sixth annual meeting of the American Academy of Neurological Surgery will be held at the Percy L Jones General Hospital Battle Creek Mich, September 17-18 with hotel headquarters at the Hart Hotel Brig Gen Joseph E Bastion M C U S Army, commanding general of the hospital will give the address of welcome Major Frank H Mayfield M C, A U S will deliver the presidential address on 'Some Notes on the History of the Army Medical Department' Speakers will be

Lieut Jo e M Ferrer Jr M C A U S Penicillin Therapy
Capt Preston C Iverson M C A U S Skin Grafting for Decubitus Ulcers
Col Robert H Kennedy M C A U S The Use of Local Anesthetics
Col Walter B Martin M C A U S Malaria A Military and Public Health Problem
Lieut Col Paul A Petree M C A U S The Psychoneuroses with Emphasis on the Battle Reaction
Major Paul L Cuck M C A U S Common Problems Associated with the Optic Nerve
Major Ross M Newman and Capt James G Irving M C A U S Care of Neurogenic Bladder
Lieut Col David Reeves M R C Some Unusual Cranial Neoplasms Encountered at the Hoff General Hospital Santa Barbara Calif
Major Barnes Woodhall M C A U S Demonstration of the De Jong Stimulator
Capt George S Baker M R C New Methods of Treatment for Osteomyelitis of Skull in War Casualties
Dr Rupert B Ramey Los Angeles The Similarity of Symptoms Resulting from Certain Cauda Equina Tumors and Herniated Intervertebral Disk
Dr John E Raaf Portland Ore Electroencephalographic Studies Immediately Following Head Injury
Dr Theodore C Erickson Madison Wis The Cortical Representation of the Sacral Segments
Dr A Earl Walker Chicago Studies on Concussion
Lieut Comdr Charles Hunter Sheldon (MC) U S N R Observations on Monkey Cerebrum Through Lucite Calvarium

There will be a roentgenologic conference Saturday conducted by Lieut Col Joseph C Bell M C A U S and a symposium on amputations by Major Mayfield Capt Fred F Senerchia Jr M C A U S Lieut Col Francis McKeever M C A U S and Comdr James C White (MC) U S N R

Approve Expansion of Firms for Manufacture of Penicillin—Nine companies have received authority from the War Production Board to build new facilities to increase the production of penicillin the New York Times reported on August 30 Four of the concerns and three others have been producing the drug but five are entering as newcomers in the field it was stated The total cost of the expansion for the nine firms will exceed \$3,000,000 Although the army gets only 50 per cent other units of the armed forces as well as maritime workers receive their share and large supplies are needed for continued research and tests Control of the drug for civilian use is vested in Dr Chester S Keefer Boston chairman of the committee on chemotherapeutics National Research Council By agreement of the agencies working to develop penicillin every gram allocated to civilians goes to Dr Keefer and he passes it along to hospitals for clinical tests or to specific physicians The nine companies which have applications approved for expansion are the Abbott Laboratories North Chicago \$2,000,000 Reichel Laboratories Kimberton Pa for its laboratories at Phoenixville Pa \$532,831 Upjohn Company Kalamazoo Mich \$100,000 Bayer Company a division of Sterling Drug Company Inc manufacturing for Winthrop Chemical Company at Kenilworth N Y \$50,000 Commercial Solvents Corporation Terre Haute Ind \$41,700 Eli Lilly & Co

Indianapolis \$370,000 Lederle Laboratories, Inc Pearl River, N Y \$880,596 Schenley Research Institute, Lawrenceburg Ind \$24,781, and Cutter Laboratories Berkeley Calif, \$420,664 Abbott Reichel Upjohn and Winthrop were already producing penicillin as well as the Merck Company of Rahway, N J Charles Pfizer & Co of Brooklyn and E R Squibb & Co of New York City, which had already enlarged their facilities

LATIN AMERICA

Health Activities in Latin America—In July a five year maintenance plan was proposed for Central America covering projects in Costa Rica Nicaragua Honduras El Salvador and Guatemala according to the Newsletter of the Health and Sanitation Division of the Coordinator of Inter-American Affairs The plan was submitted by Dr Eugene P Campbell field director for Central America and Lieut Col Henry W Van Hovenberg chief of party in El Salvador Maintenance would consist in expenditures for labor to make repairs in malaria control ditching, sewage disposal plants health centers and slaughterhouses

Public Health Conference—The Central American Public Health Conference in El Salvador, July 12-16, included field trips and conferences Projects visited were the malaria control work in Sonsonate and Acajutla, the health center in Santa Tecla the health center in Santa Ana, the malaria control work and sewage treatment plant in San Miguel, and the venereal disease clinic in El Salvador Among the subjects discussed at the conference meetings were the feasibility of combining care and preventive measures in health centers the problem of malaria control, tuberculosis control, child hygiene control of communicable disease, health education statistics and laboratory procedures

Construction—In Bolivia the uncompleted construction of the former Italian Club in La Paz was purchased to house the ministry of health and health center The building of a hospital is under consideration at Guayaramerin New health centers are planned for Bolivar, Colombia and in Ecuador a new health center and dispensary will be erected in Quito renovation has started on the children's clinic there Approval has been given to plans to reinforce the medical school building at the University of Guayaquil The erection of a new hospital is planned in Manta and the completion of one in Bahia de Caraquez An important undertaking in Tegucigalpa is the construction of a building to serve as a public health department for Honduras and the public health center for the city The building is located in the center of the town on a site donated by the Honduras government

Health Education—In Brazil the ministry of health and education has authorized the establishment of a fellowship program in addition to the program now operating under the direction of the Institute of Inter-American Affairs Ninety-three scholarships for the National School of Nursing have been provided by the various departments in Colombia

Care for Rubber Workers—Interest in the medical care of rubber workers in the republics is evidenced in the various plans set up In Colombia plans have been completed for a 40 bed hospital at Miraflores and for 30 bed institutions at La Chorrera and Aracua Under construction are 20 bed floating hospitals for use on the Caqueta and Putumayo rivers The floating units will weigh about 70 tons and be constructed on wooden flat bottomed barges The construction of small dispensaries has been approved by the Rubber Development Corporation on the banks of rivers to supplement the larger hospital units In Guayaquil Ecuador twelve dispensaries planned in the medical care program for rubber workers are now in operation only four stations are accessible by regular means of communication the others requiring either mule or canoe trip Three practical doctors were sent to the Mosquitoia portion of Honduras during June to supply medical aid to the rubber gatherers the chief of the group will be stationed at Brewers Lagoon This is a part of a program recently launched to care for rubber tappers in remote malaria infested jungles of Central America by a new type of roving doctor (THE JOURNAL July 17 p 822)

Personal—Dr John J Phair epidemiologist in the division of health and sanitation left Washington on August 6 to spend about six weeks in Chile as a consultant in methods of controlling meningitis Dr George C Dunham director of the division of health and sanitation returned to Washington on August 2 after an extended trip to Mexico Brazil Panama and Colombia Dr Charles Cadwallader medical officer with the field party in Brazil was sent to Bogota Colombia August 17 for four months to assist in the development of a program for marine air inspection quarantine regulations to the Colombian government

July 17, 1943

Army Medical Service in the Field

Lieut. Gen. Sir Alexander Hood, director general of the army medical services, has described the steps taken to adapt the medical services in the field to the needs of modern warfare. The essence of the new organization is the more advanced stations of surgeons and the swifter provision of surgical treatment. The new chain of evacuation of casualties differs slightly from the old. It is (1) the regimental aid post, (2) the casualty collecting post, (3) the advanced dressing station, (4) the field dressing station, (5) the advanced surgical center, (6) the casualty clearing station and (7) the general hospital. For the second link in the chain, the casualty collecting post, there is a new type of officer, who is not a doctor but is frequently drawn from the personnel of the army medical corps. He is equipped with a motorcycle, and his duty is to expedite and organize the rearward movement of casualties.

At the third link, the advanced dressing station, is stationed a surgeon who examines the casualties, and on his judgment their further movement depends. Those requiring an urgent operation bypass the next link, the field dressing station, and are taken straight to the fifth, the advanced surgical center. Those suffering from shock go to the field dressing station for resuscitation treatment. All other cases, having had their front line treatment completed, miss out two links and go straight to the casualty clearing station.

The advanced surgical center marks the greatest improvement in the system. It contains a field dressing station, a field surgical unit and a field transfusion unit. The field surgical unit is new and saved many lives in North Africa. It consists of a surgical team with equipment for one hundred operations and is provided with 20 beds in case it is desirable to retain patients for a time. When circumstances permit nursing, sisters are attached to it. This is the most advanced point at which they serve.

Another innovation is the parachute field ambulance surgical team, which is dropped with the troops with its equipment in containers. This was used last November in Tunisia, and numerous operations were performed not only on British troops but on German prisoners and on Arabs wounded in air raids. Lieut. C. G. Rob, the first paratroop doctor to win the military cross, performed a heroic feat. When dropped by parachute he broke his leg. Nevertheless he carried on. When the blood transfusion supplies gave out he took a pint of his own blood for a patient. The citation states that he performed some one hundred and forty operations after being dropped by parachute, in many cases under enemy bombing.

In the North African campaign a unique incident took place. A British officer was director of the medical services of all the allies engaged and there was the fullest cooperation. On one occasion the Americans urgently required a 200 bed hospital. It was provided by the British and actually flown to the point where it was required.

Among other novelties are the Nuffield anesthetic apparatus, which enables ether to be administered in the tropics, formerly difficult if not impossible, and the chloroform capsules, used to get the seriously wounded out of tanks.

Leprosy in the British Empire

At a meeting of the British Empire Relief Association it was stated that there are still over 2 million persons with leprosy in the British Empire. The money now available under the Colonial Development and Welfare Act allows our colonies

to provide adequate measures of prevention and treatment. It was suggested that a second research station, besides the one at Calcutta, should be established, with facilities for training leprosy workers. Sir Cuthbert Sprawson pointed out that seventy-one years after the discovery of the leprosy bacillus there is probably more leprosy in the world than when it was discovered. But there was another side to the picture. In the past twenty to thirty years the care of persons with leprosy had improved and the atmosphere of leprosy hospitals had changed to one of hope. The benefit given by the hydnocarpus oils, introduced in 1916 by Sir Leonard Rogers, drew patients to the hospitals and allowed the doctor to instruct the patient and the public. We have learned that it is of no use to attempt propaganda and preventive treatment among a primitive population unless it is combined with curative treatment. Increased knowledge of nutrition has helped, for poverty, entailing insufficient and improper feeding, is an important predisposing cause of leprosy. Knowledge of prevention has increased, but methods of segregation must be adapted to local customs and prejudices. Field research has shown that many persons with mild attacks of leprosy recover spontaneously, sometimes without knowing that they have had the disease. We have learned how important it is to keep the patients exercised and occupied in some useful work. Special institutions are necessary for those who have passed through the contagious stage but are left crippled or are too old or too feeble for work.

Restoration of Museum of Royal College of Surgeons

The wrecking of the greatest pathologic and anatomic museum in the world—that of the Royal College of Surgeons—by German bombs has been described previously (*THE JOURNAL*, July 8, 1941, p. 58, Feb. 28, 1942, p. 747). Nearly two thirds of the specimens were destroyed, including much that was irreplaceable, such as the Hunterian collection. Within a few weeks the council of the college set up a committee under the chairmanship of Prof. Grey Turner to plan a new museum based on the surviving specimens and the traditions of the old but adapted to present conditions, which differ vastly from those of a hundred and fifty years ago when the museum was founded by the government's purchase of John Hunter's great collection. The museum was then the only one of the kind, but now every medical school has formed its museum. The museum will be devoted to the development, structure and functions of man and his diseases. Comparative anatomy will be retained only as far as it throws light on the anatomy and functions of the human body in health and disease. Anthropology will be retained, but greater discrimination will be used in this subject. The Hunterian collection will be restored as far as possible by replacement of the destroyed specimens and by making copies of models based on records, illustrations or recollection. It will not be separately exhibited but distributed among the appropriate sections.

It is recommended that the museum shall consist of two sections—anatomy and pathology—and that the council shall establish chairs for the control of these chairs of human and comparative anatomy and human and comparative pathology. For reconstituting the series of anatomic dissections the committee has obtained the help of leading teachers of anatomy. The object is to display the structure of the body from every possible aspect and at all ages, comprising normal (including microscopic) anatomy, topography and applied anatomy, surgical anatomy, embryology and senile changes. Restoration of the pathologic collections offers less difficulty. Selected members of the Royal Society of Medicine are being organized to make a systematic collection. Regional pathology will be developed primarily for the expert, as the needs of the student are largely met by the museums of the medical schools. There will be sections of military surgery, forensic medicine and

industrial diseases, also a historical section which will include Hunterian and post-Hunterian relics and one devoted to the evolution of modern surgical instruments. A new feature is a series of X-ray films or lantern slides of films and exceptional cinematographic films of surgical conditions and operations.

BRAZIL

(From Our Regular Correspondent)

July 15 1943

Special Public Health Service for the "Rubber Army"

Dr George C Dunham Medical Corps U S Army, and director of the Division of Health of the Bureau of the Coordinator of Inter-American Affairs arrived at the Calibouço airport of Rio de Janeiro July 11 during the course of an inspection trip of the health and sanitation projects now under way in Brazil. Mr Jefferson Caffery, American ambassador in Brazil Dr Dunham and Hon Gustavo Capanema minister of health of Brazil signed a contract a few months ago to start a medical and sanitary organization named Serviço Especial de Saude Publica (Special Service of Public Health) and known as the SESP, to take charge of the main tasks of the health work in the Amazon basin where there are millions of rubber trees loosely scattered over the largest fluvial basin in the world, and in the Rio Doce valley where large iron deposits are located besides some relatively minor projects, like the construction and operation of a first class nursing school at the University of São Paulo. Both in the Amazon basin and in the Rio Doce valley tropical malaria is highly prevalent. The American representative of the Division of Health of the Coordinator of Inter-American Affairs in Brazil is Dr George M Saunders a specialist in tropical medicine with many years of practice of this kind of work in the Virgin Islands and in West Africa. Important sanitary engineering projects are being carried out at and around the cities of Belem state of Para, and Manaus state of Amazonas (present populations 220 000 and 115 000 respectively). Smaller drainage projects are being executed at secondary fluvial harbors such as Altamira Breves Santarem Rio Branco, Val de Cans and Porto Velho where sanitary centers have been organized to introduce health education and propaganda and medical and sanitary assistance into adjoining areas. Six large launches are being built to develop this medical work, and twelve smaller motor boats are already at work with doctors nurses and pharmacists. This is the beginning of a future large fleet of medical floating clinics to be operated beside many more fixed dispensaries which will be located at the most strategic points in connection with endemic malaria. In Santarem a special hospital with 50 beds is being built and in Breves a first class large malaria clinic is in course of organization. The headquarters of the whole Amazon health organization is in Belem, at the mouth of the river where a great entomologic laboratory is already functioning. A subordinate laboratory will be created at Manaus 1 000 miles up river. Many thousand immigrants from the semiarid northeastern states of Brazil have been moved to the Amazon basin and this human flow called the Rubber Army is continuing to be driven into the area. This is a tremendous task because the rubber collecting workers have to be attracted subjected to a careful medical examination educated in the principles of individual malaria control and effectively protected against the disease during the trip mainly overland through malaria infested districts. An important work to be done from the very beginning is the dietetic education of these backward agricultural workers and the effective protection of them against many more health hazards including venomous snakes. A chain of medical centers and food dispensing establishments has been organized along the inland routes and special dietitians have been placed at these medical

centers. In the Rio Doce valley the work is not so well developed yet as in the Amazon basin but previous surveys have demonstrated that malaria is also very prevalent in the region. As minor tasks of the SESP there are several training centers for medical specialists, nurses, nurses aides, laboratory technicians and sanitary inspectors.

Brief Items

Dr Edgard Schneider, president of the University of Porto Alegre, Rio Grande do Sul, Brazil, has been invited by the U S government to visit the principal universities of the United States. The University of Porto Alegre includes five institutions: the Law School, the Medical School, the Engineering School, the School of Pharmacy and Dentistry and the School of Sciences.

Dr Ernani S Pereira has been appointed chief of the medical service of the Division of Personnel of the municipality of Rio de Janeiro, succeeding Dr João B Canto whose death has been reported in a previous letter.

Drs Paulo Eljalde and Nilton Costa presented to the Brazilian Anatomic College a paper on the pathology of silicosis in the gold mines of Brazil. The lecture was illustrated by photographs, photomicrographs, X-ray films and anatomic specimens of the cases presented. They discussed the correlation of the disclosed lesions with pneumonitis and with tuberculosis. For some time silicosis has been studied in Brazil particularly in connection with the Morro Velho and the Passagem gold mines and several interesting papers have been published by Drs C M Teixeira M Curti E Macedo O Barbosa M Moreira and Araujo Lima in the scientific bulletins of the National Department of Mineral Production.

Dr Aloysio de Castro professor of medicine at the University of Rio de Janeiro has been elected president of the Brazilian Academy of Medicine.

Dr Clementino Fraga recently retired as professor of medicine of the University of Rio de Janeiro has been elected professor emeritus by the University of Salvador, state of Bahia. Before being professor at Rio de Janeiro Dr Fraga held the same position for several years at the University of Salvador.

Dr Barbosa Vianna professor of pediatric surgery and orthopedics at the University of Rio de Janeiro has been elected to the presidency of the Brazilian Anatomic College.

Death of Dr Antonio Fontes

Dr Antonio Cardoso Fontes director of the Oswaldo Cruz Institute, has died at the age of 64. As soon as he received his medical degree Dr Fontes began to work as an assistant of Oswaldo Cruz in 1902 in the preparation of antiplague serum and vaccine for the first time in Brazil to combat a disease that had entered the country through the ports of Santos and Rio de Janeiro. This serologic work was the origin of the present Oswaldo Cruz Institute at Manguinhos near Rio de Janeiro. After the work against plague Dr Fontes followed Oswaldo Cruz as one of his principal assistants in the campaign to eradicate yellow fever from Rio de Janeiro (1902-1903). As an investigator at the Oswaldo Cruz Institute Dr Fontes specialized in the study of the tubercle bacillus. He is known as the inventor of a special method to stain the bacillus and as a pioneer in the demonstration of the filtrable phase in the life cycle of the bacillus. Dr Fontes was a member of several Brazilian and foreign scientific associations. The scientific papers of Dr Fontes are numerous particularly in the fields of plague (1902-1903) and the biology of the tubercle bacillus (1910-1935). In the last few years Dr Fontes was deeply interested in the problem of cancer this being the reason of his last visit to the United States in 1942. He succeeded Dr Carlos Chagas in 1934 as director of the Oswaldo Cruz Institute in which post his administrative work is as laudable as his scientific studies. A few months ago his name was placed in the Brazilian Book of Merit.

Deaths

Edward Ross, Brooklyn University of Louisville School of Medicine, 1936, diplomate of the National Board of Medical Examiners, appointed first lieutenant in the medical reserve corps, U S Army June 26, 1936, reappointed first lieutenant on June 26 1941, served with the 245th Coast Artillery Regiment from Jan 11, 1941 until May 10, 1942, when he was relieved from active duty and reverted to inactive status, was honorably discharged on May 5, 1942 by reason of physical disqualification, promoted to temporary captain, Army of the United States, Feb 1 1942, named ship surgeon in the U S Merchant Marine in June 1942 aged 30 died recently in the Medical Center, Stephen A Harkness Pavilion for Private Patients New York, of acute pancreatitis

Samuel Ernest Fletcher, Chicopee, Mass, Boston University School of Medicine, 1892 served two terms as mayor of Chicopee, city bacteriologist and formerly city physician, for several years chairman of the library commission, member and chairman of the school committee and board of health, examiner for the Selective Service System recently and also during World War I, served as president of the chamber of commerce, director of the Chicopee Cooperative Bank and the Cabot Trust Company, a member of the staff of the Wesson Maternity Hospital, Springfield, consulting physician, past president and for many years chief of the staff of the Wesson Memorial Hospital, Springfield, where he died, June 22, of carcinoma of the bone, aged 76

Robert Lee Bradley * Roswell, N M, University of Louisville (Ky) Medical Department 1890, councilor of the Fifth District and past president of the New Mexico Medical Society, formerly member, vice president and secretary of the New Mexico Board of Medical Examiners served as president of the Pecos Valley District Medical Society, fellow of the American College of Surgeons, a captain in the medical corps of the U S Army during World War I, at one time mayor of Roswell, served as president of the Roswell National Bank and as vice president of the First State Bank and Trust Company, member of the staff of St Mary's Hospital, aged 76, died, June 19, of uremia

Calvin Edward Bradley, Tulsa, Okla, Barnes Medical College, St Louis, 1905, member of the Oklahoma State Medical Association, Oklahoma State Pediatric Society and the American Academy of Pediatrics, specialist certified by the American Board of Pediatrics, Inc, vice president and formerly a member of the state board of medical examiners, served as a captain in the medical corps of the U S Army and later with the British army during World War I, was decorated by the British government for gallantry, on the staffs of the Hillcrest Memorial and St John's hospitals, aged 58, died, July 6, of heart disease

John Wilson Elder * Albuquerque, N M, Western Pennsylvania Medical College, Pittsburgh, 1892, a major in the medical corps of the U S Army during World War I, active in the National Guard in Pennsylvania and New Mexico, for many years surgeon in charge of the Santa Fe Coast Lines Hospital, formerly associated with the Indian Service, served as superintendent of the Laguna Sanatorium for Tuberculosis, recently district health officer for Bernalillo and Sandoval counties, had been health officer in several districts in New Mexico, aged 78, died, June 9, of cerebral hemorrhage

George Woodruff Williams * Trenton, N J, Georgetown University School of Medicine, Washington, D C, 1917, a member of the state board of medical examiners from July 1939 to February 1942, fellow of the American College of Surgeons, visiting surgeon at the state prison, served as a lieutenant in the U S Navy during World War I, surgeon on the staff and director of the intern committee of St Francis Hospital, aged 50, died, June 20, in the Graduate Hospital of the University of Pennsylvania, Philadelphia, of a brain tumor

Benjamin F Akin, Jackson, Ga, Georgia College of Eclectic Medicine and Surgery, Atlanta, 1899, member of the Medical Association of Georgia, secretary and past president of the Butts County Medical Society on the staff of the R F Strickland and Son Memorial Hospital, Griffin, aged 73, died, June 12, of heart disease

Elmer David Augspurger * Lodi, Calif, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907, served on the staffs of the

Buchanan and Mason hospitals, aged 62, died, June 25, in San Francisco of acute catarrhal jaundice

Frederick T Avery, Palos Park, Ill, Northwestern University Medical School, Chicago, 1894, aged 74, died, June 19, in the Englewood Hospital, Chicago, of hypertension, heart disease and pulmonary edema

James T Baker, Huntington, W Va, University of Virginia Department of Medicine, Charlottesville, 1901, aged 74, died, July 19, of coronary thrombosis

Robert O Ball, Tacoma, Wash, Eclectic Medical Institute, Cincinnati, 1893, aged 75, died, June 18, of pernicious anemia

Marion Thomas Beaman, Eva, Okla (licensed in Oklahoma in 1932), aged 81, died, June 6, of chronic nephritis

Axel P Bergman * New Haven, Conn, University of the City of New York Medical Department, New York, 1895, member of the American Roentgen Ray Society, aged 74, radiologist to the Hospital of St Raphael, where he died, June 18, of carcinoma of the stomach

William Troy Bivings Jr * Atlanta, Ga, Cornell University Medical College, New York, 1932, member of the staffs of St Joseph Infirmary and the Emory University Hospital, aged 36, died in the New York Hospital, June 15, of anterior mediastinal mesothelioma with metastases

Joseph L Boehm * New York, Missouri Medical College, St Louis, 1899, adjunct professor of urology at the New York Polyclinic Medical School and Hospital, at one time professor of genitourinary surgery at the St Louis College of Physicians and Surgeons, member of the American Urological Association, fellow of the American College of Surgeons, on the staff of the Bellevue Hospital, aged 66, died, June 29, of heart disease

Frank Bernard Broderick, Detroit, Detroit Homeopathic College, 1904, veteran of the Spanish-American War and World War I, formerly member of the city council, coroner of Wayne County and city physician, served on the staff of the Grace Hospital, aged 63 died June 17, in the Veterans Administration Facility, Dearborn, Mich, of myocardosis

Arthur Eugene Brown, Greenville, Pa, Western Reserve University Medical Department, Cleveland, 1902, member of the Medical Society of the State of Pennsylvania, served during World War I, aged 66 on the staff of the Greenville Hospital, where he died, June 10, of cardiorenal disease

Frank Reitz Buchanan, Canton, Okla, Chicago College of Medicine and Surgery, 1914, medical examiner for the local draft board, aged 51, died, June 4, of coronary occlusion

Thomas Dickinson Burgess * Williamson, W Va, University of Maryland School of Medicine, Baltimore, 1892, aged 73 died, June 24, of heart disease

Edward Ward Burns, Honesdale, Pa College of Physicians and Surgeons, New York, 1894, member of the Medical Society of the State of Pennsylvania, for many years a member of the school board of Honesdale, served as medical examiner for several insurance companies, surgeon for the Erie Railroad for thirty years, aged 71, died, June 21, in the Wayne Memorial Hospital of a streptococcal infection

Charles James Carey, Towson, Md, College of Physicians and Surgeons, Baltimore, 1897, for many years superintendent of the Eastern Shore State Hospital, Cambridge, aged 72, died, June 24

John B Corsiglia, Brooklyn, Long Island College Hospital, Brooklyn, 1897, aged 72, died, June 11, of heart disease

Edgar Eugene DeLa Perriere, Winder, Ga, Chattanooga (Tenn) Medical College, 1909, also a druggist, aged 58, died, June 8, in St Mary's Hospital, Athens, of uremia

Marie Adelheid Dies, Buffalo, Illinois Medical College, Chicago, 1904, aged 67, died, June 7, of myocarditis

Loyal Lindsey Dunlop * Madrid, N Y, Albany Medical College, 1916, past president of St Lawrence County Medical Society, served as coroner of St Lawrence County, health officer for the towns of Madrid and Louisville, served during World War I, member of the staffs of the A Barton Hepburn Hospital, Ogdensburg and the Potsdam Hospital, aged 52, died, June 14, of coronary thrombosis in Ottawa, Ont, Canada

Edward Everett Higdon, Fredericktown, Mo, Barnes Medical College, St Louis, 1903, member of the Missouri State Medical Association, past president of St Francis Iron Madison-Washington-Reynolds Counties Medical Society, aged 73, died in Ironton, May 28, of bronchopneumonia and hypertension

Guy Munford Kendall, Corder, Mo Kansas Medical College Medical Department of Washburn College Topeka, 1908, aged 65, died in the Research Hospital, Kansas City, June 17, of carcinoma of the splenic flexure

Allison Jardine Laird, Des Moines, Iowa, University of the City of New York Medical Department 1887, aged 85 died June 8 of myocarditis and hypertension

Henry Elmer Laymon, Warren Ind., Medical College of Indiana Indianapolis 1897, formerly president of the First National Bank, aged 75 died June 19

William Lechner & Hartford Conn. Baltimore Medical College 1910 fellow of the American College of Surgeons for many years surgeon of the city fire department served during World War I one of the founders, chief surgeon and head of the medical defense unit Mount Sinai Hospital consulting surgeon to the Hartford and St Francis hospitals, aged 59, died suddenly, August 10 of coronary thrombosis

Edward Austin McManus, Los Angeles L R C P Ireland and L R C S Ireland 1923 on the staff of the Queen of Angels Hospital, aged 53 died June 3 of coronary thrombosis

Philip George Manecke, Brooklyn University of the City of New York Medical Department 1893 member of the Medical Society of the State of New York, aged 79, a founder and surgeon in chief of the Bethany Deaconess Hospital where he died June 8 of cerebral hemorrhage and hypertension

Martin Luther Matthews, Sanford N C University of North Carolina School of Medicine Raleigh 1903 member of the Medical Society of the State of North Carolina aged 68 died June 12 in the Lee County Hospital

Wallace Bruce Matthews, Grand Rapids, Mich., Chicago Homeopathic Medical College 1890 aged 81 died, June 3 in the O Keefe Sanitarium East Grand Rapids of Parkinson's syndrome

William Wilson Maxwell, Mavview Pa University of Pennsylvania Department of Medicine Philadelphia 1896, served during the Spanish-American War and World War I, aged 69 senior resident physician to the Mavview State Hospital, where he died July 2, of coronary thrombosis

Eben P S Miller, Chicago Harvey Medical College, Chicago 1905 member of the Illinois State Medical Society, medical examiner for the Selective Service Board number 123 served on the staffs of the Garfield Park Community and Franklin Boulevard hospitals, aged 70 died June 16, of coronary thrombosis

James Lyons Miller, Waukegan Ill Loyola University School of Medicine Chicago, 1916 veteran of the Spanish-American War served on the staffs of St John's Hospital, Largo N D the Victory Memorial and St Therese's hospitals at one time health officer of North Chicago, aged 71, died, June 25 of cerebral hemorrhage

William Joseph Monaghan, Secaucus N J Medico-Chirurgical College of Philadelphia 1896 served during World War I formerly superintendent of the Hudson County Hospital aged 72 died June 26 in the Fitch Memorial Hospital Neptune of myocardial failure

Samuel Moore, Chicago, University Medical College of Kansas City Mo, 1898 member of the Illinois State Medical Society member of the staff of the Garfield Park Community Hospital, aged 71 died June 15, of arteriosclerotic heart disease

Frank Beattie Morrissey, St Paul, University of Minnesota Medical School Minneapolis 1919 member of the Minnesota State Medical Association fellow of the American College of Physicians specialist certified by the American Board of Internal Medicine served during World War I and as a major in the Minnesota National Guard on the staff of St John's Hospital aged 51 from 1920 to 1933 a member of the staff of the Veterans Administration Facility Minneapolis where he died June 16 of cirrhosis of the liver

William A J Mosley, Thomasville, Ga Meharry Medical College Nashville Tenn, 1895 aged 71 died June 24 of cerebral hemorrhage

Otto Louis Mulot, Brooklyn University of the City of New York Medical Department New York 1889 served during World War I aged 75 for many years on the staff of the Brooklyn Hospital where he died, June 22, of acute yellow atrophy of the liver

James J Murphy, Annapolis Md University of Maryland School of Medicine Baltimore 1896 served as health officer and physician medical examiner for the draft board during

World War I and recently chairman of the examining physicians of the local Selective Service Board, aged 68, on the staff of the Emergency Hospital, where he died, June 26, of diabetes mellitus and carcinoma

Joseph Francis Nagle & Youngstown Ohio, Georgetown University School of Medicine, Washington, D C, 1919, surgeon for the Pennsylvania Railroad, aged 48 member of the staff of St Elizabeth's Hospital, where he died, June 13 of coronary thrombosis

Vivian John Neale & Chicago, Bennett Medical College, Chicago, 1915, on the staff of St Bernard's Hospital, aged 50, died June 28, of cerebral hemorrhage

Edward Lewis Neff, Pittsburgh Western Pennsylvania Medical College Pittsburgh 1891 member of the Medical Society of the State of Pennsylvania aged 84, died, June 15, of intestinal obstruction

Dorothy Nina Agee Rich, Lava Hot Springs Idaho University of Tennessee College of Medicine Memphis 1920, member of the Idaho State Medical Association, aged 45 died, June 5 of pneumonia

Frederick W Rich, Charlotte Hall, Md Chicago Homeopathic Medical College, 1889, the Hahnemann Medical College and Hospital Chicago 1905 served on the staff of the Washington County Hospital, Hagerstown, aged 84 died, June 3, in the Relax Sanitarium of chronic myocarditis

Francis Leslie Richardson, Weiser Idaho Chicago Medical School 1925 aged 52, died, June 22 in the Veterans Administration Facility, Boise of heart disease

Carroll Bancroft Rugh, New Alexandria, Pa, Jefferson Medical College of Philadelphia 1885 member of the Medical Society of the State of Pennsylvania bank president, aged 82, died, June 11 in the Westmoreland Hospital, Greensburg, as the result of an injury received in a fall

Walter Burns Ryder, Long Beach, Calif, Chicago Homeopathic Medical College 1899 aged 75 died June 4, of cerebral sclerosis and acute cardiac dilatation

Mark Page Stanley, Northboro Mass, Baltimore Medical College 1895 aged 69 died, June 10, in the Memorial Hospital Worcester, of coronary thrombosis

Herbert P Wilson & Wynne Wood Okla, Vanderbilt University School of Medicine, Nashville, Tenn, 1893 an Affiliate Fellow of the American Medical Association, the first councilor of the Seventh District of the Oklahoma State Medical Association at one time physician in charge of the Wynnewood Sanitarium, aged 85, died May 1, of cerebral sclerosis

DIED WHILE IN MILITARY SERVICE

Allen Ashton Altman, Berkeley Calif Stanford University School of Medicine, San Francisco, 1939 member of the California Medical Association began active duty as a lieutenant junior grade, in the U S Naval Reserve Sept 7 1942 aged 28 was accidentally shot and killed in the North Pacific area April 11

George Howes Ketler & Menands N Y University of Buffalo School of Medicine 1934 assistant in medicine at the Albany Medical College from 1937 to 1939 and later an instructor in medicine, served on the staffs of the Albany and Memorial hospitals Albany, began active duty as a captain in the medical reserve corps of the U S Army in October 1940 a flight surgeon in the Army Air Corps aged 32 was killed July 21 in an airplane crash in the Latin American area

Ben Robbins, Pittsburgh University of Tennessee College of Medicine Memphis 1937 began active duty as a first lieutenant in October 1940 and later was commissioned a captain in the medical reserve corps of the U S Army a flight surgeon attached to the Air Corps aged 30 died June 5 of a fractured skull in the North African area (non-battle casualty)

Samuel W Wein & New York Long Island College Hospital Brooklyn 1925 fellow of the American College of Surgeons served on the staffs of the Lebanon and Jewish Memorial hospitals began active duty as a captain in the medical corps Army of the United States Sept 9 1942 aged 42 died in Camp Campbell Ky July 20 of coronary thrombosis

Bureau of Investigation

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *THE JOURNAL*. Following are brief abstracts of some fraud orders not dealt with previously.

Brown Remedies Company—Under this name and the names J A Brown, Dr Brown and J A B, one J A Brown, a farmer living on a rural route outside the town of Bremond, Texas, conducted a mail order scheme for about fifteen years selling various products that he termed "botanicals" for the treatment of different diseases. A complaint to the Post Office Department from a dissatisfied customer caused that agency to investigate Brown's enterprise. An inspector for the department entered into a test correspondence with Brown to learn how he did business. An inquiry was addressed to Dr Brown stating that the writer had diabetes was on a diet and wondered what Brown could do for him. Brown replied that the treatment for this case would cost \$5.10. At another time he intimated to the same inquirer that the latter had cancer but could be cured by Brown's botanicals for \$28.50. On the receipt of some money Brown sent his patient a shipment containing small packages of herbs. Two chemists in the employ of the Government reported that their examinations showed the treatment to consist of four preparations containing, respectively, gentian dandelion root, dried flower of red clover and ground root of burdock. In December 1942 the Post Office Department notified Brown to show cause on Jan 1, 1943 at its Washington office why a fraud order should not be issued against him and the various names under which he operated. Brown replied in a series of three letters but did not appear at the hearing or send any counsel to represent him. The Government offered as its witness at the hearing Dr Fred W. Norris, Senior Medical Officer of the Food and Drug Administration, Federal Security Agency, as one well qualified to give expert medical testimony. Dr Norris testified that the selection of a proper mode of treatment required in a particular case necessarily was based on an accurate diagnosis, a process which in itself necessitates physical examination by a competent practitioner involving use of the hands of the examiner and often the utilization of instruments, x-rays, blood tests and other laboratory procedures. He showed that a reading of the list or description of symptoms set forth in the cited letters addressed to Brown would not enable any one to determine just what specific disease entities were present, and without such determination it would be impossible to prescribe proper treatment. Dr Norris testified further that he was familiar with the herbs comprising the "treatment" and that the total effect of these preparations would be approximately the equivalent of that obtained from the drinking of a cup of hot water together with use of a mild appetizer. He showed further that dandelion, red clover and burdock are rapidly being discarded by medical science and no longer appear in the United States Pharmacopoeia, whereas gentian has no recognized specific value in the treatment of any known disease entity and acts merely as a bitter or stomachic. Also he said, the dietary advice prescribed under the circumstances mentioned would be worse than useless and in the case of a person suffering from many ulcerated or inflammatory conditions of the gastrointestinal tract it would be harmful. Brown's letter in answer to the memorandum of charges stated that he sold botanicals by mail but denied that he made any claim "as to the curative effects of any roots or herbs." The evidence definitely established, however, that Brown was representing through the mails that he could effectively treat various diseases with the herbs that he sold, and consequently the findings were that he was attempting to obtain remittances of money through the mails by means of false and fraudulent pretenses, representations and promises. A fraud order closing the use of the mails to the names J A Brown, Brown Remedies Company, Dr Brown and J A B was issued by the Post Office Department on Feb 6, 1943.

L H Forte—From Hattiesburg, Miss., this person conducted a medical business by mail, representing that he could cure whatever ailed a customer. Though Forte put the title "Dr" before his name, no evidence could be found in the exhaustive biographic files of the American Medical Association to show that he ever attended a medical school or was licensed to practice medicine in any state. It was, in fact, his unwarranted selling of alleged cures, accompanied by medical advice that led to the investigation of his scheme by the Post Office Department. A letter sent to him, asking whether he had any medicine that would cure diabetes, brought the reply that he could cure the writer and restore her to "perfect health" with a treatment for which he asked \$12.50. On appeal from the inquirer he reduced the price to \$5, which amount was sent him. In return, Forte mailed the customer a liquid consisting essentially of oil of citronella, and a package composed of 40 per cent of epsom salt and 60 per cent of sulfur. With these he sent instructions for taking, and some additional advice. When the Post Office Department, after due investigation of Forte's quackery, notified him to show cause on Oct 22, 1942, why a fraud order should not be issued to debar him from further use of the mails, he neither appeared at the hearing nor sent anyone to represent him. At that hearing Dr Fred W. Norris, Senior Medical Officer of the Food and Drug Administration, testified that the treatment described above was utterly worthless for diabetes. Also the hearing brought out that Forte had represented through the mails that for \$10 he would "guarantee" a cure with his treatment without even knowing what diseases the inquirers might have. The investigation of his business had elicited from him the statements that he had commenced the enterprise in 1935 that it consisted in selling

by mail only certain "powders" and "sights," and that he did not practice medicine or sell cures. All these claims the investigation proved false. Accordingly, the Post Office Department, on Nov 17, 1942, issued a fraud order debarring Forte from further use of the mails.

Manks' School of Natural Healing Southern School of Natural Healing and "Dr" Sanford B Manks—Under these names one Sanford B Manks, who at times used the "degrees" ND and DMK after his name, conducted a mail order scheme from Deland, Fla., selling a correspondence course in the study of naturopathy or drugless healing. The Post Office Department charged Manks with representing that all persons who completed the course, regardless of their former education, would be legally qualified to establish offices for the practice of naturopathy or drugless healing in any of the states in the Union that as a result of taking the course they would be fully qualified and able to diagnose accurately and prescribe for and treat any and all diseases suffered by mankind and cure such conditions as cancer, diabetes, cirrhosis of the liver, gall stones, typhoid fever, measles, mumps, chicken pox, arthritis, infantile paralysis, scabies, pneumonia and erysipelas. In August 1942 the Post Office Department called on Manks to show cause on Sept 14, 1942, why a fraud order should not be issued against him and the several names under which he operated. He replied with a letter which made general denial of all the charges and submitted a number of alleged testimonial letters from various persons with whom he had had dealings. Manks, however, neither appeared at the hearing in Washington nor sent counsel to represent him. At that hearing the Government introduced as exhibits various advertisements taken from magazines and other periodicals in which Manks offered the opportunity to "become Drugless Practitioners," "Learn the Healing Science of the Ages—the Laying on of Hands," "Learn Drugless Therapeutics, Practice Naturopathy and Metaphysical Healing," and "Study the coming profession. Become a Drugless Practitioner and Metaphysician, practicing under the Chirothesian Certificate." A mass of other exhibits also was introduced, consisting of letters and typewritten statements sent by Manks through the mails in answer to inquiries. It was shown that in some of these he had represented himself as "a retired Naturopathy Practitioner, Drugless Physician, and Metaphysician, of about 45 years' practice, study, research and experimentation, 'qualified to teach you the rational principles to be used in restoring the sick body to health,' and as having the 'degrees' of 'ND, CC TS'." It was shown that the Post Office inspector who had investigated this case had visited and interviewed Manks at his place of business and discovered that Manks maintained his residence and office entirely in one automobile trailer which was parked in the yard of the house in which his wife and daughter lived. That the trailer was a small ordinary type and that the interior was equipped with a bed at one end and a portable typewriter and merger office equipment at the other end. It contained no scientific equipment such as one would expect to find in a medical school. Manks told the inspector that he had once engaged in the cleaning and laundry business at Portland, Maine, and moved to Deland, Fla., in 1939. What he was selling through the mails was, he declared, "the vast amount of knowledge" acquired during a lifetime. He claimed to have the equivalent of a high school education but was unable to furnish the names of any institutions from which he had graduated except that he exhibited a diploma from the Blumer College of Naturopathy, Hartford, Conn., dated June 5, 1932, which school he stated was now out of existence. Manks admitted that he was not a physician, chemist or pharmacist. Dr Fred W. Norris, Senior Medical Officer of the Food and Drug Administration, gave expert medical testimony for the government at this hearing to the effect that he had examined all of the "lectures" comprising the course of study sent out by Manks and was of the opinion that this alleged course would in no way enable a student thereof to diagnose or cure human diseases. Many of the theories set forth in these lectures, he stated, contradicted other theories expressed in the same course. Further, he testified that a person taking such a course would not be qualified to pass or even to take any examination required by law in any of the states of the Union before the issuance of a license to practice any medical profession concerning the treatment of human diseases. Since the testimony in the case was considered sufficient to show that Manks's scheme constituted a fraud on the public, it was debarred from the mails on Nov 13, 1942.

Tesano Tea Company Inc—This New York concern, whose manager was in Elmer H. Baden, sold through the mails a nostrum known as "Tesano Tea" and represented, in advertisements placed in various periodicals and through written and printed matter sent through the mails that if taken as directed it would control diabetes, reduce the sugar content of blood and urine, restore the diabetic person to a more normal condition and relieve the symptoms of diabetes without the use of insulin or dietary measures. A microscopic examination made by a microanalyst in the employ of the Food and Drug Administration at Washington showed that Tesano Tea was a coarsely ground mixture of chamomile flowers, juniper berries, anise seed, caraway seed, fennel seed, senna leaves, equisetum stems, mint leaves, mallow flowers, strawberry leaves, and a substance closely resembling bilberry (the common European form of huckleberry). A chemist for the Food and Drug Administration made a chemical analysis of the tea brewed from this mixture according to the directions and reported that the mineral matter found in the water soluble portion amounted to 1.43 sodium and potassium salts, 0.05 iron, 0.07 calcium, 0.15 sulfate and minute traces of other minerals found in herbs soluble in water, together with tannin from barks and chlorophyll from the leaves of these herbs. In August 1942 the Post Office Department ordered the Tesano concern to show cause at a hearing to be held on August 28 why it should not be debarred from the use of the mails for perpetrating a fraud on the public in the sale of this tea. After various postponements the hearing was finally held on October 1 and the Post Office at that time introduced all of its evidence. In addition to the evidence on the composition, mentioned above, expert

medical testimony for the government was given by Dr. Maurice Protas, a physician well qualified by education and experience to give such testimony. He stated that he had made a careful study of diabetes and had treated several thousand sufferers from that disease and testified that the use of the Tesano Tea according to the composition as shown by the analysis reported would have no beneficial effect on a diabetic condition would not reduce the sugar content of the blood or urine or in any way alleviate the symptoms of the malady or restore a diabetic person to a normal condition. Further he testified that should such a person use this tea and relax his dietary precautions or discontinue the use of insulin (if taking it) in the belief that Tesano Tea would permit of such discontinuance and relaxation he might grow progressively worse and go into a diabetic coma and die. The Tesano company was represented at the hearing by its attorney who requested additional time within which to present expert medical testimony. The respondents were given until October 8 to introduce such testimony and thereafter the time was extended until November 2 at their request. However there was received from the attorneys for the respondents a letter dated Nov. 20, 1942 in which he stated that after consultation with his client company the latter as the result of a medical opinion they had received concerning their product had decided to discontinue the sale of Tesano Tea and to return all remittance received to the senders besides shipping all herbs on hand back to the concern from which they had been purchased. Further the Tesano people offered to dispose of their fixed assets so that the corporation would either be dissolved or considered abandoned. Despite these representations the Post Office Department felt that the defendant concern or its successors or agents might at some time decide to resume their fraudulent enterprise and to prevent this a fraud order depriving the scheme from the mails was issued on Dec. 14, 1942 against the Tesano Tea Company, Inc.

CEASE AND DESIST ORDERS

Abstracts of Certain Federal Trade Commission Releases

The work of the Federal Trade Commission in helping to protect the public against misrepresentation or fraud in the medical as well as other fields has been greatly extended by the provisions of the Wheeler-Lea Amendment to the Federal Trade Commission Act. The Food Drug and Cosmetic Act of 1938 added to the Food and Drug Administration's control of the advertising claims and statements made on the label of a medicine or on the carton or in the accompanying leaflet, whereas what might be termed collateral advertising, that which appears in circulars, newspapers and magazines and over the air, comes more actively under the purview of the Federal Trade Commission by virtue of the Wheeler-Lea Amendment.

THE JOURNAL has at various times commented on the activities of the Federal Trade Commission in this connection, even before the Wheeler-Lea Amendment gave it its added rights. In some cases the Commission may accept from the person or concern involved a stipulation that the objectionable practices or claims cited will be discontinued. In other cases the Commission issues what is known as a Cease and Desist Order in which the individual manufacturer or distributor cited is ordered to cease and desist from practices which have been declared objectionable. In some cases the claims cited have been discontinued by the firms several months (or even longer) before the issuance of the order. Abstracts of some of the orders issued in 1942 follow in this form: name of product, name of distributor, date of issuance of complaint, date of issuance of Cease and Desist Order and terms of order.

Bee Dew Cosmetics—Lillian S. Nash trading as Bee Dew Cosmetic Company, Detroit, complaint issued Aug. 18, 1942, order issued Oct. 30, 1942. Order directed the respondent to discontinue any advertising which represented that Bee Dew Special Hair Grower, Bee Dew U. Gro., Bee Dew Special U. Grow, Bee Dew Scalp Oil, Bee Dew Shampoo, and Bee Dew Pressing Oil promote the growth of new hair or constitute a cure or remedy for or possess any value in the treatment of falling hair, baldness, dull hair, scalp irritation or dandruff, beyond cleansing the hair and scalp, allaying itching due to minor scalp irritations and facilitating the removal of loose dandruff scales or any advertisement which uses the word grow or grower or any term similar to these in phrasing or tending to describe the preparations designated Bee Dew Special Hair Grower, Bee Dew Special U. Gro. and Bee Dew U. Gro. or which otherwise represents that any such product has any effect on the growth of the hair. The respondent was ordered further to discontinue any advertisement which represents that her product Bee Dew O. No. will give complete protection from offensive body odor or have any effect thereon in excess of affording temporary protection from such odors.

Chinese Herbs—Edwin Tom trading as Master Herb Company, Los Angeles, complaint issued April 21, 1942, order issued Oct. 4, 1942. Order prohibited any advertisement representing that these herbs constitute a cure or remedy for rheumatism, arthritis or asthma or possess any value in treating such conditions in excess of giving temporary relief from the symptoms of pain associated with rheumatism and arthritis and temporary relief from the pains of a rheumatism or any advertisement

representing that such herbs possess therapeutic value in treating any other diseases or ailments beyond affording temporary palliative relief from some of the pains or other symptoms that accompany them. Also prohibited were the representations that the herbs in question are a cure or remedy for or have any value in the treatment of stomach ulcers or that their use will renew the glands of the body or enable the user to regain strength or vigor.

Di Function—Di Function Company, Inc., Fort Worth, Texas, complaint issued Jan. 13, 1942, order issued Nov. 6, 1942. Order prohibited further advertising, misrepresentations that the product is a cure or effective treatment for sugar diabetes will revive the glands of the pancreas or enable them to produce sufficient insulin for the body's needs or enable a victim of sugar diabetes to discontinue dieting and the use of medicines with safety.

Double Vitamin Cold Cream and Skin Softening Cream (formerly called Ward's Tissue Cream)—Montgomery Ward and Company, Chicago, complaint issued March 21, 1942, order issued October 16, 1942. Order prohibited the concern from further representing that any of its cosmetic preparations containing vitamins A and D have therapeutic value when applied to the skin or any effect on the appearance of the skin beyond the emollient, soothing and cleansing action of ordinary cosmetic cream mixtures. That the presence of vitamins A and D in these products gives them special properties over and above those of ordinary cosmetic creams or that the use of such toiletries because of their vitamin content will have any beneficial effect in keeping the facial skin firm and smooth or the hands soft, smooth and white or in promoting growing skin or retarding the appearance of age. The Ward concern also was prohibited from further use of the words tissue cream or similar terms to describe any cosmetic preparation or from representing in any way that its creams have therapeutic value in treating or nourishing the skin tissues.

Electro Health Short Wave Diathermy—Electro-Health Appliance Company, Los Angeles, complaint issued June 12, 1941, order issued Nov. 10, 1942. Order directed the concern to discontinue any advertisement which represented that the device is harmless and constitutes a competent treatment for the various ailments mentioned in the advertising or any other disorder unless specifically limited to cases in which no acute inflammatory process is involved and in which the application of heat is not likely to induce hemorrhage or any advertisement which fails to reveal clearly, conspicuously and unequivocally that the device is unsafe to use unless a competent medical authority has determined as a result of diagnosis that the use of diathermy is indicated and has prescribed the method of such treatment and the user has been thoroughly instructed by a physician or trained technician in the use of the device.

Hollywood Magic Garment—Hollywood Magic Garment Company, Los Angeles, complaint issued Feb. 11, 1942, order issued Jan. 26, 1943. Order prohibited dissemination of any advertising which represented that this device constitutes an effective method for the removal of excess flesh or weight or that it is in all cases safe to use. This order was based on the findings of the Commission that the garment in question made of rubberized cloth which fits tightly about the neck, wrists and ankles induces perspiration and thus causes the body to lose substantial quantities of water salt and consequently weight. The findings continue, however, that the effect is only temporary since the wearer of the garment because of thirst produced by the amount of water lost must proceed almost immediately to drink a quantity of water or other liquid with the result that the weight of the body becomes about the same as it was before the process was begun. The Commission also found that the device cannot be properly regarded as safe in all cases as its use may raise body temperature to such a point that heat exhaustion will follow and it should never be used in the presence of any serious pathological condition when the debilitating effect of the loss of fluid and salt from the body would be distinctly detrimental.

Pescor Shortwavatherm—Physicians Electric Service Corporation, manufacturer Solomon E. Mendelsohn, officer and the Navy Department Store Company, sales agent, all of Los Angeles, complaint issued Jan. 31, 1942, order issued Oct. 27, 1942. Order prohibited further use of misrepresentations in the advertising of the product in question a short wave diathermy device as follows: that the thing resulted from years of diligent engineering research and incorporated safety features that physicians prescribe and recommend short wave diathermy in many ailments (of which more than 40 were named in the advertising) that even the unskilled lay public can use this device in the treatment of self diagnosed diseases and ailments by individual self application in the home and that it will prove a scientific harmless and effective method of relieving or curing arthritis, sinus infection, lumbago and other conditions.

SNL (Suffer No Longer)—Cora Lee Wiley, Adel, Ga., complaint issued Dec. 22, 1940, order issued Nov. 6, 1942. Order prohibited further advertising misrepresentations that this product constitutes a cure or remedy for or possesses any value in the treatment of gonorrhea or any disease or disorder of the female organs.

VBV—Purity Products, Inc., distributor Newark, N. J., The Journal of Living Publishing Corporation, advertiser and Victor H. Lindlacher, editor or the latter two of New York, complaint issued Feb. 10, 1940, order issued Feb. 12, 1943. Order prohibited the respondents from further disseminating any advertisement which represented that VBV has any value in the treatment of arthritis, nervousness, indigestion, sleeplessness, lack of energy, underweight or general run-down condition or any disease or condition caused by or associated with a vitamin B deficiency. Respondents were further ordered to cease representing that the product will beneficially affect any manifestation of vitamin B or vitamin G deficiency or the assimilation or absorption of food to increase weight or that it is anything more than a food supplement capable of supplying certain vitamins which can be obtained from ordinary foods.

Correspondence

GRANULOCYTOPENIA AFTER USE OF SUCCINYL-SULFATHIAZOLE

To the Editor —I am much interested in an article which appeared in *THE JOURNAL*, July 3, reporting the death of a patient alleged to be due to acute agranulocytosis due to the administration of succinylsulfathiazole. I feel that it is highly important that all toxic manifestations, especially the more serious ones such as acute agranulocytosis following the administration of the sulfonamides be given special consideration. I do not, however, feel it at all desirable that questionable occurrences of drug sensitivity should be reported dogmatically as being due to the sulfonamides. In this report it appears that the patient was probably sensitive to sulfathiazole, and I should like to refer to one such observation which I reported in a paper entitled "Succinylsulfathiazole: An Adjuvant in the Surgery of the Large Bowel" (*THE JOURNAL*, Sept. 26, 1942, p. 265). Under the subtitle "Toxicity of Succinylsulfathiazole" an instance was reported of a moderately severe reaction to succinylsulfathiazole. The patient was subsequently shown to be highly sensitive to sulfathiazole, and it was emphasized that any patient receiving succinylsulfathiazole should be under close observation.

I do not agree fully with the conclusions of the article. Unfortunately, mention was not made as to whether or not this patient had been on a restricted diet, although reference was made to an article by Spicer, Daft, Sebrell and Ashburn, "Prevention and Treatment of Agranulocytosis and Leukopenia in Rats Given Sulfanilylguanidine or Succinylsulfathiazole in Purified Diets" (*Pub. Health Rep.* 57:1559 [Oct. 16] 1942), involving observations made on animals on highly restricted, purified diets. Also, unfortunately, the author has not given any data as to the white cell count on the February 9 admission, although the statement is made that "repeated blood counts revealed rapidly developing acute agranulocytosis" and the question is raised as to whether all of these counts were done after the patient had developed a sore throat. I am fully aware of the possibility that a sensitive individual may react to a relatively small quantity of drug, however, I am not aware of any instance in which acute agranulocytosis has developed in the patient when the quantity of drug in the blood was so low that it could not be detected by the usual quantitative colorimetric procedure. It is not my purpose to detract from a proper report showing the toxicity of succinylsulfathiazole, but I cannot agree that this is a proved case of acute agranulocytosis due to the administration of succinylsulfathiazole, and I am unable to find in the literature any support for the following concluding statement: "Sensitivity has been shown to be present not only when there has been an interruption in the course of medication but also when there has been a prolonged administration of large doses of the drug." I am unable to find where succinylsulfathiazole was referred to in any of the references given. In fact, the original publication announcing succinylsulfathiazole was not written until 1941 (Poth, E. J., and Knotts, F. L. *Proc. Soc. Exper. Biol. & Med.* 48:129 [Oct.] 1941).

EDGAR J. POTH, PH.D., M.D., Galveston, Texas
Professor of Surgery, University
of Texas Medical Branch

[NOTE—This letter was referred to Dr. S. A. M. Johnson, who replies.]

To the Editor —The subject matter of the article entitled "Succinylsulfathiazole: An Adjuvant in the Surgery of the Large Bowel" is familiar to me. The toxic reactions of succinylsulfathiazole are undoubtedly due to sulfathiazole, a product

of its hydrolysis. Therefore in any sulfonamide hypersensitive individual receiving succinylsulfathiazole reactions peculiar to sulfathiazole are to be anticipated.

In referring to the article by Spicer, Daft, Sebrell and Ashburn, "Prevention and Treatment of Agranulocytosis and Leukopenia in Rats Given Sulfanilylguanidine and Succinylsulfathiazole in Purified Diets," I applied the treatment used for the experimental agranulocytosis and did not mean to emphasize the part that diet played in its production. Incidentally, my patient was on a regular hospital diet until he became too ill to eat.

The results of the blood examinations, which were on a chart that was deleted from the original paper, were: Feb. 13, 1943, white blood cells 8,500 with a differential count of polymorphonuclears 65 per cent, basophils 1 per cent, small lymphocytes 22 per cent and mononuclears 7 per cent; February 16, white blood cells 7,200; February 26, white blood cells 7,000 and March 1, white blood cells 1,400 with a differential count of polymorphonuclears 30 per cent, small lymphocytes 62 per cent and mononuclears 8 per cent. On the morning of March 2 the white blood cell count was 1,200 with a differential count of small lymphocytes 90 per cent and mononuclears 10 per cent. In the afternoon the white blood cell count was 500. On the morning of March 3 the white blood cell count was 500. In the evening of March 3 the white blood cell count was 200 with a differential count of small lymphocytes 14 per cent and large lymphocytes 86 per cent. The first blood examination which showed a drop in white blood cell count and in polymorphonuclear count was taken on the morning the patient first experienced a sore throat.

A sternal puncture examination was done on March 3. This also was deleted from the original paper. It revealed a marrow which was moderately cellular. There was a complete absence of myelocytes with fairly numerous myeloblasts showing no evidence of maturation. There were numerous megalocytes, many phagocytic endothelial cells and occasional plasma cells. The development of granulocytes was stopped at the primitive blast and myeloblast stages.

In a hypersensitive individual toxic reactions may manifest themselves with the administration of almost minute quantities of a drug. These reactions at the same time are not dependent on the blood concentration. Levin and Bethell in their report "Fatal Granulopenia Developing During the Administration of Sulfadiazine" (*Univ. Hosp. Bull., Ann Arbor* 8:30 [April] 1942) stated that the blood concentration of the sulfonamide derivatives gives no indication of the likelihood of ensuing granulocytopenia. Likewise Rinkoff and Spring in their article "Toxic Depression of the Myeloid Elements Following Therapy with the Sulfonamides" (*Ann. Int. Med.* 15:89 [July] 1941) stated that the dosage of the drug, not the blood concentration, is probably the factor that determines whether a toxic manifestation could occur in a susceptible individual. Also Lyons and Balberor in their article "Febrile Reactions Accompanying the Readministration of Sulfathiazole" (*THE JOURNAL*, March 21, 1942, p. 955) state that it is possible to produce such a high degree of hypersensitivity to the drug that a very small dose may elicit a febrile response.

The sentence "Sensitivity has been shown to be present not only where there has been an interruption in the course of medication but also where there has been prolonged administration of large doses of the drug" did not refer entirely to succinylsulfathiazole per se but to the sulfonamides in general and to sulfathiazole in particular. I wish to reemphasize that succinylsulfathiazole most likely owes its toxicity to sulfathiazole, a product of its hydrolysis. The following statements taken from various papers are of interest: Rinkoff and Spring,

in discussing the toxicity of the sulfonamides (Toxic Depression of the Myeloid Elements Following Therapy with the Sulfonamides, *Ann Int Med* 15 89 [July] 1941), state that although a small dose may cause a leukopenia or fatal agranulocytosis these toxic effects on the bone marrow usually manifest themselves after prolonged use especially in the instances in which the disease itself has a deleterious effect on the hemopoietic system. Havne and Larimore (Sulfathiazole as a Cause of Death, *THE JOURNAL*, Oct 18, 1941, p 1353) said that their patient was the first example as far as they knew of an apparently well person in whom acute agranulocytosis developed after prolonged medication with sulfathiazole during which time no other drug was used. Lee Thompson (Agranulocytosis Due to Sulfathiazole *North East Med* 41 133 [April] 1942) commented in his case of agranulocytosis due to sulfathiazole that interruption or administration seems to be the most important factor in fatal cases. Levin and Bethell (Fatal Granulocytopenia Developing During the Administration of Sulfadiazine, *Univ Hosp Bull, Ann Arbor* 8 30 [April] 1942) in speaking of sulfonamide derivatives stated that granulocytopenia usually develops after prolonged or interval use of such drugs. Long, Haviland, Edwards and Bliss (The Toxic Manifestations of Sulfanilamide and Its Derivatives, *THE JOURNAL*, Aug 3, 1940, p 364) found that patients who have a toxic reaction caused by one of these drugs may have a similar reaction when another member of the sulfonamide group is prescribed. Lyons and Balberor (Febrile Reactions Accompanying the Readministration of Sulfathiazole *ibid* March 21, 1942, p 955) stated that it is well known that antigenic agents may often be administered continuously without any deleterious consequence, but, if an interval is interposed between courses of the antigen, hypersensitive reactions are apt to occur.

STURE A M JOHNSON, M.D., Ann Arbor Mich

USE OF LIVER TO OVERCOME TOXICITY OF SULFONAMIDES

To the Editor—This communication is prompted by the Current Comment in the July 17 issue of *THE JOURNAL*, page 812. It concerns the remarkable findings by Chamelin and Funk that injections of whole liver reduced the toxicity of sulfanilamide and diethylstilbestrol in rats.

Certain experiments that I have done lead me to believe that the action of whole liver extract in ameliorating the toxic effects against both of these substances is through its high content of ascorbic acid. It has long been known that liver, next to the adrenal glands, contains more ascorbic acid than all other animal tissues (Aron H., and others *Jahrb f Kinderh* 1 123 1921).

The effect of ascorbic acid in reducing the toxic effects of neorhaphenamine is also well known (Sulzberger, M B, and Oser B L *Proc Soc Exper Biol & Med* 32 716 1934). Recently I was able to reduce the sensitivity of a patient to large doses of salicylates by the concurrent administration of vitamin C (*J Lab & Clin Med* 28 28 [Oct] 1942). Others and myself have been able to reduce the toxicity of the sulfonamides by concomitant administration of vitamin C in large doses (Pulner Louis *Acad New York State J Med* to be published).

Recently also I was able to give to 3 patients effective doses of diethylstilbestrol even though they were previously remarkably sensitive to exhibition of this drug. This was done by giving a preliminary intravenous injection of ascorbic acid

(100 mg) and giving 100 mg of ascorbic acid by mouth with each tablet of diethylstilbestrol. This was reported in a lecture on vitamins in a postgraduate course in gastroenterology (May 17, 1943 at the Greenpoint Hospital). This lecture is to be published in the *American Journal of Digestive Diseases*.

How vitamin C improved the tolerance to certain chemical drugs is unknown. One author (Aulstey, M *Prat med franc* 18 107 [March] 1937) is of the opinion that vitamin C acts by assuring the vitality and proper functioning of the liver cells.

LOUIS PELNER, M.D., Brooklyn

"QUINACRINE-CALCIUM THERAPY OF TYPHUS"

To the Editor—In your editorial comment "The Quinacrine-Calcium Therapy of Typhus" in the July 24 issue the work of Dr van Meerendonk is described with a closing remark that opinion about it cannot be ventured until further experiences are reported.

Permit me to call your attention to an article on "The Use of Atabrine in Two Cases of Typhus Fever," published in the April 1943 issue of the *Medical Bulletin of the Veterans Administration*. While the German investigator's work antedates mine no mention of it was made in a medical publication of any United Nation until an abstract of this treatment appeared in the October 1942 issue of the *Tropical Diseases Bulletin* (London) and so recorded by the *Quarterly Cumulative Index Medicus*.

As seen from the report of the 2 cases of typhus in the *Medical Bulletin of the Veterans Administration*, no knowledge of Dr van Meerendonk's work could have been available when the effects of the drug on typhus were first noted at this hospital. While no priority for the use of atabrine in treatment of typhus can be claimed by the undersigned I respectfully submit my article published in the *Medical Bulletin of the Veterans Administration* as evidence of an independent discovery of the use of atabrine in the treatment of typhus.

It may be added that a report of 2 more typhus cases apparently successfully treated with atabrine has been submitted for publication to the *Medical Bulletin of the Veterans Administration*.

HAROLD FREED, M.D.
Veterans Administration Hospital,
Dallas 2, Texas

DUSTING POWDER FOR RUBBER GLOVES

To the Editor—In the issue of April 17 you kindly published a note from me, recommending starch as a substitute for talcum as a dusting powder for gloves. At the time that letter was written there was reason to believe that we (M G Seelig, D J Verda and F H Kidd) had overcome the undesirable gelatinization property of starch. We were in error and therefore were obliged to institute a new search. We have now found that potassium bitartrate is a completely satisfactory substitute for talc. The potassium bitartrate in addition to being free from all the undesirable and dangerous properties of talc, possesses the highly desirable property of being bacteriostatic. Several of our leading St. Louis hospitals have used the potassium bitartrate with complete satisfaction and safety.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts State Law not Applicable to Practice on Grounds for Public Buildings Ceded by the State to the United States—Lynch, who was licensed to practice medicine and surgery in Tennessee but not in Arkansas, rendered on a site of land purchased by the United States government "medical first aid work" to approximately 2,000 employees of a contractor engaged in the construction in Arkansas of a colony for Japanese evacuees. The Desha county chancery court, Aug 19, 1942, enjoined him from practicing medicine in Arkansas without a license so to do. The next day he filed a writ of prohibition in the Supreme Court of Arkansas against the chancellor of the Desha chancery court to prevent the chancellor from proceeding further in the injunction suit. The Supreme Court issued a temporary writ of prohibition against the chancellor, which was made permanent about six weeks later. The chancellor moved for a rehearing.

The sole question here present, said the Supreme Court, is whether a physician not licensed in Arkansas, who confines his practice to workmen engaged in constructing federal buildings on property owned by the United States, is subject to the laws of Arkansas relating to the practice of medicine and surgery. Admittedly the state of Arkansas has yielded jurisdiction over the area in question by reason of section 5644, Pope's Digest, which provides, in part, as follows:

"The state of Arkansas hereby consents to the purchase to be made or heretofore made by the United States, of any site or ground for the erection of any armory, arsenal, fort, fortification navy yard, custom house, lighthouse, lock, dam, fish hatcheries, or other public buildings of any kind whatever and the jurisdiction of this state within and over all grounds thus purchased by the United States, within the limits of this state, is hereby ceded to the United States Act April 29, 1903, p 346, sec 1

Article 1, section 8, clause 17 of the constitution of the United States provides that Congress shall have power

to exercise exclusive Legislation in all Cases whatsoever, over such District (not exceeding ten Miles square) as may, by Cession of particular States, and the Acceptance of Congress, become the Seat of the Government of the United States, and to exercise like Authority over all Places purchased by the consent of the Legislature of the State in which the Same shall be, for the Erection of Forts, Magazines, Arsenals, dock yards, and other needful buildings

We think, continued the Supreme Court, that there can be no doubt that the buildings constructed by the government on its property to be used for the relocation of the Japanese come within the term "other public buildings of any kind whatever," as used in section 5644, supra, and under the aforementioned provisions of the United States constitution as "other needful Buildings," in this time of war stress. The Supreme Court of the United States in *Surplus Trading Company v Cook*, 281 U S 647, 50 S Ct 455, held that certain blankets located within Camp Pike on land owned by the United States and lying within Pulaski County, Ark (now known as Camp Robinson), are not subject to taxation by this state because Arkansas has surrendered and ceded its jurisdiction over the area to the United States, the court there saying:

It long has been settled that, where lands for such a purpose are purchased by the United States with the consent of the state legislature the jurisdiction theretofore residing in the state passes, in virtue of the constitutional provision, to the United States, thereby making the jurisdiction of the latter the sole jurisdiction

The War Department of the United States by proclamation No WD 1, issued Aug 13, 1942, has designated the property in question here as a military area

We think, continued the court, that the issue here has been decided against the chancellor's contention by this court in *Loung v G L Tarlton, Contractor, Inc*, 162 S W (2d) 477. In that case it was charged that two Delaware corporations engaged in constructing military buildings for the United States at Camp Robinson were violating the laws of this state because they had failed to qualify in Arkansas as foreign corporations. This court, however, rejected that contention, saying:

The laws of this state relative to the domestication of foreign corporations have no application for the reason that appellees were engaged in construction work for the United States at a military post under the jurisdiction of the United States

In the case under consideration, said the Supreme Court, it is conceded that Dr Lynch is confining his practice to the area owned by the United States, administering to the employees of the construction company, which by contract with the United States is required to keep available a physician for its employees. We think it clear, under the aforementioned authorities, that the laws affecting the practice of medicine and surgery in Arkansas do not control and cannot apply to the rights of Dr Lynch to practice on property the jurisdiction over which has been surrendered to the United States, and the title to which has been acquired by the United States. The writ of prohibition against the chancellor preventing him from proceeding further in the original injunction suit against Dr Lynch was affirmed.—*Lynch v Hammock*, Chancellor, 165 S W (2d) 369 (Ark., 1942)

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1943 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents in one and 15 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be ordered for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Electrocardiograms in Pulmonary Embolism.—Murnaghan and his collaborators report 10 cases of acute cor pulmonale without underlying heart disease with five deaths. The electrocardiograms corroborate the observation that there is a typical electrocardiographic pattern in acute cor pulmonale. It is characterized by right axis deviation with a prominent S wave in lead 1, a depressed ST segment in lead 2 and often in lead 1, a Q wave and an inverted T wave in lead 3 and a diphasic or an inverted T wave in lead 4-F. An upward convexity of the ST segment in lead 3 is common, an elevation of the ST take off in this lead occurs in a few cases. The electrocardiographic changes in an additional series of 92 cases of pulmonary embolism are reviewed. Coexistent heart disease was present in 69. In 29 cases symptoms of shock predominated, in 63 signs of pulmonary inaction without shock or collapse predominated. Electrocardiographic changes indicative of acute cor pulmonale were present in 16 of the former group and in 17 of the latter. Thus the electrocardiogram gave indication of some degree of acute cor pulmonale in a little more than one half of the cases when shock predominated, in a little less than one fourth of the group without shock and in about one third of the entire series, including patients with abnormal electrocardiograms as the result of heart disease. Pulmonary embolism and acute cor pulmonale are not synonymous terms. Varying degrees of acute cor pulmonale occur and the electrocardiogram provides a means of evaluating the status of the heart especially when clinical signs indicative of right-sided heart strain are not obvious. Anoxemia produced by a pulmonary embolus may cause inaction in the cardiac muscle already the seat of a severe coronary artery disease. When this occurs the electrocardiographic changes are atypical and confusing. Death is often caused by a second or third embolus. Prophylactic leg exercises, venography and ligation of the femoral vein should reduce the incidence of fatal pulmonary emboli.

Chemotherapy in Ophthalmology.—Bellows points out that penicillin, tyrothricin and related substances are more potent than the sulfonamides but that the ophthalmologic literature contains practically no reference to these substances. He tried tyrothricin experimentally and found that when it is placed in the conjunctival sac in 0.5 per cent suspension it is non-irritating but when used in high concentration produces considerable irritation and even cloudiness of the cornea. The substance was applied clinically in several cases of acute conjunctivitis with unimpressive results. The present report is limited to the sulfonamide drugs and mainly to sulfanilamide, sulfathiazole, sulfapyridine and sulfadiazine. Sulfanilamide or sulfapyridine given orally, sulfanilamide used topically or any

of the four most commonly used sulfonamide compounds employed with iontophoresis or combined with a wetting agent results in a chemotherapeutically adequate concentration in the ocular fluids and tissues. The action of these drugs is known to be inhibited by the secretion and detritus so commonly associated with ocular infection by local anesthetics and by factors inherent in the avascularity of the cornea. Oral administration of sulfonamide compounds frequently produces ocular indications of systemic toxicity. Topical application of these drugs to the denuded cornea retards epithelial regeneration and promotes scarring. Given orally they are effective in the treatment of ocular complications of erysipelas, gonorrheal ophthalmia, trachoma, inclusion blennorrhoea, ophthalmitis due to lymphogranuloma venereum, serpent ulcer, cellulitis of the lids and orbit endophthalmitis, panophthalmitis and sympathetic ophthalmia. Applied locally they are effective in pyogenic dermatoses, infectious blepharitis and some forms of acute conjunctivitis. Although the sulfonamide compounds have proved to be the most important addition to the armamentarium of the ophthalmologist since the introduction of organic arsenicals, they should not be used indiscriminately or be considered a panacea.

*Artificial Fever and Vitamin Therapy in Treatment of Anterior Poliomyelitis Report on Intraspinal Administration of Thiamine Chloride Combined with Artificial Fever Therapy S Stone —p 350

Artificial Fever and Vitamins in Poliomyelitis—Eleven patients with severe anterior poliomyelitis were treated by Stone with artificial fever and parenteral and oral vitamin therapy during the acute stage of the disease. Six patients received intramuscular or intravenous injections of thiamine hydrochloride and vitamins B and E orally. Five patients received the thiamine intraspinally in doses of 20 to 50 mg eighteen to twenty-four hours before the next artificial fever treatment. The oldest patient was 17 and the youngest 2½ years. All the children had complete paralysis of one or more extremities, associated with generalized tenderness and pain on motion. Four to ten fever treatments were administered to each patient with a temperature range of 103 to 105 F. The artificial fever was administered by means of an inductopyrexia cabinet. Ascorbic acid in doses of 150 to 200 mg was given to all patients while they were in the fever cabinet, together with fruit juices and saline solutions orally. The artificial fever was well tolerated. Relief of pain and spasm, improvement in circulation and texture of the skin of the affected extremities, prevention of contractures and improvement in strength of the affected muscles were the results from the combined treatment. All the children have continued in excellent health since the completion of the treatment and have shown no evidence of fibrosis or limitation of joint motions. The hospitalization time was greatly reduced in all cases. It is suggested that com-

bined vitamin-artificial fever therapy has all the advantages of the Kenny hot fomentation treatment, besides favorably influencing regeneration of some neurons not completely destroyed by the virus. The action is probably nonspecific and is due to improvement in cell metabolism and relief of local vasospasm in affected extremities. While the number of patients treated so far is comparatively small, the results in those treated in the acute stage suggested that this method is superior to methods used in the past. Its application to other types of paralysis of spinal origin has given promising results.

Chemotherapy in Pneumonia and Persistence of Pneumococci—Harris studied the persistence of pneumococci in the upper respiratory passages in 47 cases of lobar pneumonia treated with sulfonamide compounds by repeated throat cultures during the period of hospitalization. Forty-four and seven tenths per cent of the patients lost the pathogenic type pneumococcus during the administration of the drug, 170 per cent lost the pathogenic pneumococcus after the drug had been discontinued, but before discharge from the hospital, 383 per cent left the hospital carrying the pneumococcus responsible for their disease. Pulmonary complications were frequently associated with a prolonged carrier state. Heterologous type pneumococci were recovered in seven instances following the apparent disappearance of the pneumococcus type isolated on admission to the hospital. Comparison with the findings of the earlier literature reveals that the convalescent carrier rate has not been significantly reduced by the routine use of sulfonamide compounds in the treatment of pneumococcal pneumonia.

Surgical Therapy in Fractures of Skull—Munro presents an analysis of 218 cases of all types of compound fractures of the skull. Complete debridement should be done within forty-eight hours of the time of infliction of the injury or else no operation until completely healed for six to eight months. Patients should not be operated on until out of surgical shock and until the general condition warrants it. After the diagnosis has been made by palpation through the wound, the first and only dressing prior to debridement must be one that can be applied with an absolute minimum of handling. The debridement should be complete. It must be done in such a way as to avoid the spreading of bacterial contamination throughout the wound and the production of tissue necrosis. It should include the removal of all large foreign bodies. No wound that has been properly debrided should be drained. Irrigation of the wound before and during operation is condemned. Chemotherapy in the form of sulfanilamide or sulfadiazine is recommended both by mouth and in the wound, but only as an adjunct to properly conceived and executed surgery. Sulfathiazole should not be used in craniocerebral wounds.

Continuous Caudal Anesthesia in Obstetrics—Irving and his collaborators used continuous caudal anesthesia in over 200 obstetric cases. A malleable needle or fine catheter is left in the caudal canal through which an injection is made at intervals. To derive the full benefit of continuous caudal analgesia it should be withheld until uterine contractions are well established and the cervix is dilated to from 2 to 3 finger-breadths. The greatest dose with metycaine was 9,900 mg, with monocaine 2,250 mg and with pontocaine 572 mg. The longest that the catheter was in position was twenty-nine hours. Several patients have complained of pain over the sacrum the day after delivery and in 5 cases superficial skin infection developed but no abscesses. There was no apparent increase in postpartum morbidity although the second stage was definitely prolonged and there was a significant increase in operative deliveries. There were 29 cases of fetal distress (13.3 per cent) in 218 cases. A sustained fall in blood pressure was observed in 22 of 118 cases (18.6 per cent). Of the 12 instances of fetal distress in the last 118 cases 9 or 75 per cent occurred in cases in which there was a sustained low blood pressure. In each of the remaining 3 cases there was a clear obstetric explanation for the fetal distress. On stillbirth is reported for which there is no apparent obstetric reason and which was

probably a result of the caudal anesthesia. Continuous caudal anesthesia in obstetrics is not yet entirely free of danger to mother or child. Much more experience will be needed before it can be offered to the public. Until such time its use should be restricted to well staffed obstetric services.

Sulfadiazine for Carriers of Eberthella Typhosa—The favorable results of sulfonamide therapy in Shigella dysenteriae infections encouraged Hardy to extend his observations to typhoid. He used two quantitative tests designed to measure relatively the number of viable Eberthella typhosa in the lower enteric tract and in the feces. In one test fecal specimens were obtained by rectal swabs. In the other, passed fecal specimens were collected in glycerin saline preservative. A third non-quantitative cultural procedure was employed. The rectal swabs after being used for inoculating plates were dropped into tubes containing selenite F enrichment. Following incubation the swabs were again used for plating on agar. Routinely the author sought to obtain three pretreatment cultures from carriers and two from cases of typhoid. During medication and for one week thereafter cultures were taken daily. Sulfadiazine was used in the treatment of 19 chronic carriers, 4 convalescent carriers (including 1 treated as a case), 21 clinical cases and 1 clinical relapse. Quantitative cultural tests clearly demonstrated that this sulfonamide has a definite bacteriostatic effect on E typhosa in the enteric tract. The chronic carrier state was not terminated by this treatment.

Fluoride Osteosclerosis from Drinking Water—Linsman and McMurray report a case of osteosclerosis with mottled enamel of teeth severe anemia not responding to antanemic therapy and bilateral renal lesions. Diagnosis of fluoride osteosclerosis was proved by the history of a long residence in areas of endemic fluorosis and by fluorine analysis of the patient's bones and teeth. Osteosclerosis may be a dangerous sequel to the chronic ingestion of fluorine-containing water since it may give rise to a secondary anemia due to encroachment on the blood-forming marrow. There is also the possibility of kidney damage due to chronic fluoruremia. Areas in the United States in which dental fluorosis exists and where the fluorine content of the drinking water is over three parts per million should

be systematically studied by the public health authorities to determine the existence of osteosclerosis. All patients with dental fluorosis and minor and/or signs of renal impairment should have x-ray examination of the skeletal system.

Treatment of Impetigo—Pijoan and his collaborators employed a water soluble plastic (methyl cellulose, methocel) and sulfadiazine preparations for bacteriostatic plastic films. The scabs were cleansed with cotton soaked in hydrogen peroxide. As much as possible of the scab was removed without unnecessary trauma to the infected skin area. While the surface was still moist, tincture of sulfadiazine-methocel (solution I) was applied with a cotton applicator. This may be repeated several times until the entire lesion or area is thoroughly impregnated. Sulfadiazine-methocel jelly (solution II) was then applied to the entire area. The coating should be approximately 0.5 mm in thickness. It will dry within three to five minutes and will form a new film over the lesion. One treatment is usually satisfactory. Bacteriologic studies revealed that the impetigo lesions were caused by staphylococci. Bacteriologic counts were done on 0.1 cc of a twenty-four hour broth culture by the plate colony counting system. The results showed characteristic observations including the extremes of pretreatment counts. The more complete the debridement, the more satisfactory were the results. The debridement should be a cautious procedure, as trauma might induce scar formation with possible disfigurement. All lesions showed approximately the same diminution of bacteria.

Military Malaria Control—According to Russell, malaria is the principal disease hazard to troops in hyperendemic areas. Military malaria control involves (a) fixed installations, around which mosquito control measures are feasible and in which individual control measures are subsidiary, and (b) field areas,

in which troops fighting or maneuvering are on guard or sentry detail or are servicing convoys or airplanes, usually without the protection of mosquito control. Here "fighting malaria control" is required and measures of individual malaria prophylaxis are vital, with full use of suppressive antimalaria drugs, bed nets, protective clothing, sprays and repellents, and with intelligent cooperation by all ranks. True or causal prophylaxis is not certain to follow the use of any known drug. Sporozoites do not appear to be destroyed in the body by drugs. Malaria probably cannot be eradicated from a community by the use of drugs. The so-called prophylactic drugs achieve early or, better, suppressive treatment. Under combat conditions of exposure and great fatigue it is perhaps natural that suppressive treatment will be even less effective than it is in peacetime. The three drugs for malaria prophylaxis are plasmochin, atabrine (quinacrine hydrochloride) and quinine. There appears to be no justification for attempting individual or mass malaria prophylaxis by plasmochin either alone or supplemented by atabrine or quinine. Plasmochin is a polyvalent gametocide which destroys the crescents of *Plasmodium falciparum*. Doses of 0.04 Gm of plasmochin naphthoate or 0.02 Gm of plasmochin hydrochloride (1/10 grain of plasmochin) taken on each of two or three days, after meals, will generally clear the blood stream of all gametocytes. This has some value in preventing the infection of mosquitoes. It appears that atabrine in doses of 0.4 Gm of the dihydrochloride per week as suppressive treatment will be as good as or perhaps a little more effective than the use of quinine dihydrochloride in daily 5 gram (0.32 Gm) doses. The atabrine may be taken in 0.1 Gm doses twice a day on two non-successive days a week, with water and after meals. Atabrine causes no discomfort to the majority of persons. In a certain percentage there is some gastrointestinal irritation and a temporary yellowing of the skin. But the tinting of the skin will clear up after the administration is stopped, and the gastric irritation is usually temporary and mild. When severe and repeated reactions occur, quinine should be substituted. It is not clear from published reports that 0.4 Gm of atabrine dihydrochloride a week is sufficient for suppressive treatment in highly endemic areas. Possibly the dose in some areas should be 0.6 Gm a week, 0.1 Gm daily, with a double dose on Sundays. It is not clear how many months of constant atabrine prophylaxis can safely be tolerated. The limit appears to be well over six months. As many and as long intervals of freedom from atabrine as feasible should be allowed. The most important drug in malaria prophylaxis has always been quinine. It will frequently (but not always) prevent clinical symptoms. The usual prophylactic dose of quinine is 5 to 10 grains (0.32 to 0.64 Gm) of quinine daily after the evening meal. Some authorities prefer 10 grains twice a day on two or three days a week. In highly malarious areas even 15 grains (1 Gm) daily may not suppress clinical symptoms in all cases. Under present conditions quinine prophylaxis is to be used only for men who cannot tolerate atabrine.

Typhus Rickettsial Agglutination Tests—Van Rooyen and Bearcroft tested 50 military and 23 civilian typhus patients from the Middle East area for serologic evidence of agglutinins against *Proteus vulgaris* OX19 OX2 and OXK, as well as agglutinins against epidemic and murine rickettsias. Results show close correlation between the Weil-Felix and rickettsial agglutination tests. Experiments to verify the specificity of the rickettsial agglutination test have been performed on 100 normal human serums and on 74 pathologic serums from 25 cases of malaria, 12 of typhoid, 22 of sandfly fever, 4 of spirochetal relapsing fever and other febrile conditions all of which were carefully selected and accurately diagnosed. The results have shown that the rickettsial agglutination test did not give false positive agglutination in the diseases specified. The rickettsial agglutination test is a highly specific and reliable test for typhus equal if not superior to the Weil-Felix test. It possesses the advantage of differentiating between epidemic and murine varieties of infection which the Weil-Felix reaction cannot do. The principal technical disadvantage of the rickettsial agglutination test is that rickettsial agglutination is very fine and is liable to be missed whereas agglutination of *Proteus vul-*

gariis is easily visible. Both reactions become positive from the seventh day of illness on, i.e. usually two days after the rash has appeared. The agglutinin titer reaches its maximum about the fourteenth day of illness and thereafter declines at different rates. *Proteus* agglutinins recede more quickly than those for rickettsias. In a case of epidemic typhus rickettsial agglutination was still present in high titer on the sixty-fourth day after onset of symptoms when the Weil-Felix test was fast disappearing. In severe epidemic Egyptian typhus showing high titer Weil-Felix test reactions epidemic rickettsias are usually agglutinated to similar or greater serum dilutions. Simultaneously low titer cross agglutination for murine rickettsial suspensions occurs and the E R/M R ratio is approximately in the order of 3:1. In both Palestinian and Syrian mild murine typhus, which yield high titer OX19 agglutination the homologous rickettsias are strongly clumped frequently to even higher titer, with some cross agglutination of epidemic rickettsias in lower dilution the M R/E R ratio being roughly 10:1. All serums derived from patients suspected of having typhus should be tested in quintuplicate for presence of agglutinins for *Proteus* OX19, OX2 and OXK and epidemic and murine rickettsias.

Promin in Tuberculosis—Heaf and his associates used sodium p,p'-diaminodiphenylsulfone- λ -N-dioxetose sulfonate (promin) in the treatment of 19 patients with pulmonary laryngeal and genitourinary tuberculosis. The drug was given continuously for two weeks, one week's rest followed before the next fortnightly period was started. In calculating the length of treatment these rest weeks are included as the blood concentration of promin was well maintained during that period. The courses varied in length from two to fifteen weeks, the majority lasting more than six weeks and the average being eight and a half weeks. With oral administration, which was employed in 13 cases, the highest blood concentration of promin was 4.4 mg per hundred cubic centimeters, this was reached with a dosage of 0.4 Gm three times a day, the majority averaged 2.5 mg. The hemoglobin value and the erythrocyte count fell in all cases until iron was given as a routine. Toxic symptoms such as cyanosis, headache, nausea, vomiting and giddiness were also observed with oral administration of the drug. There was no tendency toward anemia or toxicity in the 2 cases in which the drug was administered intravenously. The authors think that promin should not be given by mouth to patients with advanced pulmonary tuberculosis who show toxemia and poor resistance. The local application of promin in cases of laryngeal tuberculosis is worthy of further investigation.

Strangulated Femoral Hernia—Some 115 patients with strangulated femoral hernia were treated in one institution in five years, according to Jens. A depressing feature of these admissions was the variety of diagnoses which accompanied the patients to the hospital—almost any condition capable of causing abdominal pain being suggested rather than the correct one. The surprisingly large number of 42 patients had no previous history of hernia. Reduction of strangulated femoral hernia should be accomplished by operation. The mortality for the 100 patients was 14 and of the 11 showed gangrene of the contents. Strangulation of the small intestine was found in 86 patients. In this group 20 had gangrenous bowel and the gangrene was sufficiently extensive to require resection in 12 patients, 8 of whom died giving a mortality for resection of 66 per cent for gangrenous small intestine. Of the remaining 66 patients with strangulation of the small intestine 7 died.

—all of them having intestine and omentum strangulated. A review of the time factor in the cases in which gangrene was found discloses that the patients who died had a history lasting on an average over six days whereas the patients who lived had been ill on an average for only three days. A reduction in the total mortality can be attained only by earlier diagnosis and earlier operation. Intraperitoneal sulfanilamide therapy offers hope of an improved mortality rate in cases in which resection of the bowel is necessitated by reason of intestinal gangrene.

Diethylstilbestrol in Control of Transitory Priapism

—Gaudin applies the term transitory priapism as distinct from true priapism to recurrent nocturnal erections without sexual stimulus, which are frequently the accompaniment of inflammatory lesions of the urogenital tract or are of nervous origin. He reviews 4 cases in which transitory priapism was counteracted by diethylstilbestrol. The first patient was given 0.5 mg of diethylstilbestrol daily. Relief followed on the second night. One week later the dose was dropped to 0.5 mg on alternate nights, and at the end of three weeks it was dropped altogether.

Simmonds Hypophyseal Syndrome. A. Segers, Maria E. Diaz and A. Russo —p. 218

Early Tuberculous Cavitation in an Infant.—Elizalde and his collaborators report the case of an infant 4 months of age. The mother and the child were living with a tuberculous patient for about a month. The infant was fed by the mother and was not given BCG vaccination. Several tuberculin tests gave negative results. When the infant was 3 months old both he and the mother presented clinical and x-ray signs of pulmonary tuberculosis. The roentgenograms of the infant showed signs of a cavity in the right lung. The infant died at the age of 4 months. Postmortem examination revealed acute pneumonitis and atelectasis, a cavity in the right upper lobe and foci of acute inflammation about the cavity. Microscopic examination revealed acid-alcohol resistant bacilli in the tissues near the cavity which stained with Ziehl-Nielsen stain. The cavity had the characteristics of Shmink's type of primary tuberculous cavity. Such cavities are extremely rare in pulmonary tuberculosis of infants.

*Diagnosis and Treatment of Chronic Carbon Monoxide Poisoning. Symanski —p. 192

Diagnosis and Differential Diagnosis of Multiple Myeloma by Sternal Puncture. F. Kienle —p. 195

Hiatus Hernia.—Berning differentiates three forms of hiatus hernia: (1) hiatus hernia in the presence of a congenitally shortened esophagus, (2) paraesophageal hiatus hernias and (3) hernia due to hiatus insufficiency. In the type last mentioned, in which the esophagus is not shortened, the distal end of the esophagus together with adjoining portions of the stomach become herniated. Interest in this form led to anatomic studies on changes brought about by age in the region

of the esophageal hiatus. These studies revealed that hiatus insufficiency is a preliminary stage of this type of hernia. Changes that play a part are the so-called epiphrenal bell, resulting from age involution of the left hepatic lobe and of the subdiaphragmatic ring of fat, also flattening of the diaphragm with age and increase in intra-abdominal pressure due to such conditions as ascites, obesity, chronic constipation and abdominal tumors. Factors that cause hiatus insufficiency later cause true herniation. The author cites an illustrative case history. The clinical symptoms are similar in all three forms. Roentgenologic examination is essential for a correct diagnosis. Hiatus hernia should be thought of in older patients with symptoms of gastric or duodenal ulcer, of cholelithiasis, of gastric or esophageal carcinoma or of coronary sclerosis. Careful clinical and roentgenologic examination should precede the laparotomy. In patients of advanced age medical treatment should be tried first. Increased intra-abdominal pressure is to be avoided. Patients must be cautioned against physical exertion. Meals should be small and more frequent so as to avoid filling the herniated part of the stomach. Surgery is necessary in case of threatening signs of incarceration. Operation is possible by the thoracic and the abdominal route. Harrington of the Mayo Clinic, who has operated in a large number of cases, prefers the abdominal route with reduction of the hernial aperture.

Chronic Carbon Monoxide Poisoning.—Symanski maintains that chronic carbon monoxide poisoning exists and that it may result from a succession of numerous mild acute attacks of poisoning. Carbon monoxide poisoning is usually an occupational disease which pursues a mild course. Patients complain generally of headache and nausea. The symptoms are usually absent in the morning but return in the course of the day. Later they persist longer and disappear only when work is stopped for one or several days. Finally they no longer subside. Then there may be pallor, general weakness, vomiting and nervous and neurasthenic disorders. Occasionally the patient states that co-workers have the same complaints. Investigation at the place of work may reveal the source of poisoning. Objective signs are usually slight. Polyglobulism has been observed as well as hyperchromic anemic changes. The quantitative determination of carbon monoxide hemoglobin with the step photometer is decisive in the diagnosis. Chronic carbon monoxide poisoning is chiefly a problem of industrial medicine.

Malnutrition and Vitamin C Deficiency in Dysentery

—Dotzer and Schuller have demonstrated that the resistance of guinea pigs against experimentally produced dysentery of the Flexner-Y or Kruse-Sonne-E strains was reduced by malnutrition or by vitamin C deficiency. The resistance was reduced about equally by quantitative and qualitative malnutrition. The resistance of the animals was increased by early administration of large doses of vitamin C. Guinea pigs on a high qualitative and quantitative diet were better protected against dysentery. Death of animals on a high qualitative and quantitative diet resulted from high infectious doses only. Death even from high infectious doses did not occur when the resistance of the animals on a high qualitative and quantitative diet was increased by large doses of vitamin C. The results of these experiments, as well as clinical observations on patients who are given a quantitatively differentiated diet suggest that the administration of vitamin C may be helpful both as prophylaxis and as a therapeutic measure in epidemic dysentery.

Book Notices

Allergy Anaphylaxis and Immunotherapy Basic Principles and Practice By Bret Ratner M.D. Clinical Professor of Pediatrics New York University College of Medicine New York Cloth Price \$8.70 1 p 334 with 88 illustrations Baltimore Williams & Wilkins Company 1943

The stimulus for writing this book the author says in the preface, came while he was planning a somewhat different work a treatise on allergy in childhood. Parenthetically the reviewer hopes that Ratner may soon complete this latter work. It should be good. The author states that he was impressed by the possibility of clearly presenting the difficult subjects of allergy immunology and anaphylaxis through a comprehensive discussion of serum sickness. And so one or several chapters grew into a book or rather the better part of this volume. Had the author limited himself to this excellent and comprehensive presentation of our knowledge of serum sickness and its relationship to allergy and anaphylaxis he would have published a well organized monograph of about four hundred pages instead of a book of over eight hundred pages. In addition to the presentation of the important subject of serum sickness in a most comprehensive manner he would have succeeded without dilution or distraction in presenting a somewhat simplified but excellent integration of this subject with the principles of general immunology allergy and anaphylaxis.

Following an introductory chapter, the subject would have started on page 375 (book II of this volume) with the author's discussion of allergy to immunotherapeutic agents. Here the principles of hypersensitiveness are clarified. Following this the subject of serum sickness is covered in one hundred and fifty pages. This portion reviews our current knowledge of the condition. It is crammed with valuable information. The author analyzes the significance and the clinical application to allergy of many of the fundamental investigations of serum sickness. Wherever possible the author relates animal experiments to clinical allergy. In this lies the main value of this work. To complete book II a brief but thorough presentation is made of the subject of reactions and accidents due to blood transfusions.

Book III consisting of the final one hundred and fifty pages, deals with many theoretical considerations of allergy its physiologic pathology and its relationship to anaphylaxis. An excellent presentation of the mechanism of the allergic state closes the subject. The adequacy of the bibliography and subject index which follows is indicated by the fact that it covers eighty one additional pages.

And now with regret the reviewer must speak of the first three hundred and seventy-five pages. The material contained in this part (book I) is important. It is excellent material that might have gone well in a treatise on general medicine or on general therapeutics written by a clinical immunologist. Unfortunately the subject matter of book I is not well integrated with that of book II and book III. To divide this volume as the author did into three separate books emphasizes rather than overcomes the lack of unity. In this rather irrelevant book I the author discusses such varied subjects as materials used in diagnosis and therapy of infectious diseases description and methods of preparation of materials (antisera convalescent serum transfusion materials and modes of administration preparation of toxoid and of smallpox vaccine). This is followed by a discussion of sulfonamides and sulfonamide therapy. Apparently the reason for the general discussion of the sulfonamides in this book is their therapeutic importance. While allergic reactions occur following their use a discussion of their structure and use is not relevant to the general subject of drug allergy.

Book I finally and tediously closes with two hundred pages devoted to immunotherapy. This consists of a brief discussion of the treatment of an alphabetically arranged list of diseases beginning with anaerobic infections and ending with yellow fever. This is followed by book II.

Principles and Techniques of Nursing Procedures As Developed in St. Mary's Group of Hospitals of St. Louis University [By] Sister Mary Agatha Claire D.N.S.M.B.N. B.S. in Nursing Cloth Price \$3.70 1 p 374 with 91 illustrations St. Louis C.V. Mosby Company 1943

This is an exceptionally complete and detailed manual of procedures governing every situation in which a nurse may find herself. This includes a chapter of special interest to Catholic nurses dealing with their religious obligations to Catholic patients. The book is divided into five parts of which part I consists of a single chapter having to do with arrangement of the patient's environment—that is the room the bed the care of flowers and the care of service rooms utility rooms kitchens and linen closets and the removal of stains. In part II are chapters dealing with admission procedures, patient's bath and toilet food service, elimination general comfort measures, psychologic needs and religious needs. The chapter on psychologic needs including diversional therapy flowers letters, radio visitors games handwork and library is especially good. In part II also are five excellent chapters on application of dry heat and cold hydrotherapy radiant energy and massage. Part III has two comprehensive chapters on the nurse's duty in connection with x-ray laboratory and other diagnostic tests, two chapters on surgical technic outside the operating room, four chapters on administration of medicines by various routes, one chapter on aspiration and injection of body cavities three chapters on medication applied to special systems by irrigation digestive genitourinary eye ear nose and throat and a chapter on medical aseptic nursing technic. Part IV deals with orthopedic procedures, such as splints, bandages straps traction and suspension devices, physical therapy and occupational therapy. Part V touches on the nursing care of the psychiatric patient in the general hospital. The plan of the book is to give a general description of the type and purpose of the procedure about to be described. This is followed by general instructions arranged in brief numbered paragraphs. Then follows a list of requisite equipment and a step by step description of technic. Finally a method of recording is described. The book is richly illustrated with photographs charts and diagrams. It should be a valuable textbook or reference book. It contains a chart in which a student can keep a record of each procedure described together with the date when it was demonstrated to her and by whom supervised and how many times practiced. There is an excellent index.

A Study of Endometriosis Endosalpingiosis Endocervicosis and Peritoneal Ovarian Sclerosis A Clinical and Pathologic Study By James Robert Goodall O.B.E. B.A. M.D. Consulting Staff in Gynecology and Obstetrics Royal Victoria Montreal Maternity Hospital Montreal Canada Fabrikoid Price \$5.50 Pp 140 with 30 illustrations Philadelphia Montreal & London J. B. Lippincott Company 1943

Since the classic pioneer publications of Sampson beginning in 1921 it cannot be said that there has been any substantial addition to our knowledge of this common and still rather mysterious pathologic entity. Nor can it be said that the monograph of Goodall contributes much toward its elucidation or even that it is a satisfactory review of existing knowledge.

The greater portion of the book is devoted to a discussion of types of endometriosis and the author's grouping will probably be confusing to the average reader. For example he includes among these types what he calls endometrial endometriosis (1) but his description indicates that by this term he refers to the lesion universally spoken of as hyperplasia of the endometrium. While it is possible that this may in some way be related to endometriosis this fact has not been established and there is certainly no justification in considering it a type of the latter. Another variety which would seem questionable on the basis of our knowledge is the endocervicosis referred to throughout the book.

Much of the author's discussion is along philosophic rather than scientific lines. There is scarcely a page which does not contain statements that are either highly questionable or obviously incorrect and these are uttered in a rather irritatingly oracular ipse dixit fashion. A few examples will serve to illustrate this better than many paragraphs of discussion. p 13 the action of estrin is normally limited to the superficial two

thuds of the endometrium', p 14, "traces of lack of response in endometriosis are extremely uncommon but have seldom, if ever, been described" (every trained gynecologic pathologist has long been familiar with these differences in hormonal responsiveness), p 15 "active endometriosis and pregnancy never coexist (more than 60 such cases are available in the literature), p 42 "endometriosis of whatever variety is an expression of varied endocrinology", p 61, "it is now clear—and, I think beyond all possibility of doubt—that all cases of endometriosis take their origin from some part of the endometrium" (notwithstanding the work and expressed opinions of men like Meyer and Sampson), p 79, "Endosalpingiosis is the result of subacute salpingitis", p 119 "reactions to abnormal endocrinology are chiefly in the nature of allergy", and so on.

This book is in other words largely a pirading of the author's hypotheses. As far as can be gathered, he believes that the responsible causes of endometriosis are spill and lymphatic dissemination (he constantly compares it with infection and differentiates acute and chronic forms) with such underlying factors as hyperestrinism and 'peritoneal sclerosis'. Illustrations are sparse the best being the reproductions of some of Sampson's original colored plates. The whole tone of this book is in sharp contrast to the original work of Sampson, which was a model of soundly scientific and conservatively presented investigation. One will find in many publications much less pretensions than the one under review, a far more complete survey of the problem of endometriosis without the necessity of following the author's inventive mind through many pages of pseudoscientific verbiage.

How to Keep Fit and Like It. A Manual for Civilians and a Plan for a Community Approach to Physical Fitness. By Arthur H. Steinhaus, Ph.D. M.P.I. Professor of Physiology, George Williams College, Chicago. Alma M. Hawkins, A.M. Assistant Professor of Hygiene and Physical Education, George Williams College. Lt. Comdr. Charles D. Glaue, U.S.N.R. and Edward C. Thomas, B.S. Physical Director, South Chicago Y.M.C.A., Chicago. Illustrated by I. J. Waterman. Paper. Price 25 cents. Pp. 64 with illustrations. Chicago: Consolidated Book Publishers, Incorporated, 1943.

This is a manual for persons desiring to guide their own physical fitness programs and a training textbook for instructors in group programs in communities. It is premised on sound policy and based on the experiences of trained physical directors and other experts in this field. These policies have resulted in the recommendation for pleasant and effective exercises for physical fitness. It is a small, concise volume, devoid of all "filler," and abounds in good common sense and advice. It teaches how to grade one's exercises at home, in the gymnasium or in the great outdoors. It is sufficiently illustrated to lend itself to home training and has the proper medical approach in the matter of regular physical examinations and in the development of muscles while losing excess adipose tissue. Adequate nutrition and food values are given full consideration in the fitness program outlined. It is streamlined for war service and if its program is followed systematically the reader will profit both physically and mentally. Selective Service surveys reveal not only that defects, deficiencies, diseases and disorders are present with unexpected numbers in the citizens of this enlightened country but, in addition, people as a whole stand revealed by military experience as soft, flabby, pampered and direfully in need of physical conditioning. Col. Theodore P. Banks, chief of the Athletic and Recreation Branch of the Special Service Division of the War Department, says "Many young men are entering the army today totally unprepared for military life. It takes weeks to bring them into the physical condition for military training. This means weeks of wasted time and effort, which could be avoided if every young man now in high school should engage in physical activities." This is not only true in time of national crisis but equally true in time of peace and is reflected in the lost man-hours in industry due to illness and accident caused by physical unfitness and unpreparedness and inability to carry one's full responsibility. America will profit immeasurably, economically, from a program of health and physical fitness and will derive happiness and peace of mind if disease and physical unfitness are reduced to the minimum, if not entirely eliminated. The fighting forces want only men who are "fit to fight"—young, vigorous, healthy

men in the pink of condition and with a mind to fight and a "will to win." In addition, America has the dual responsibility of supplying our fighting forces on land, in the air and on and under the sea in sufficient quantity to insure victory and, at the same time, as the "arsenal of democracy," of adequately supplying all the sinews of war required by our fighting allies. Therefore the young people of today, the men and women of tomorrow, will do their patriotic duty if they prepare themselves by becoming physically fit. This book directs them how to proceed.

Medical Jurisprudence. A South African Handbook. By Dr. W. F. Rhodes, B.A., M.B., Ch.B. Senior Pathologist, Union Health Department, Cape Town. Dr. I. Gordon, M.B., Ch.B. Assistant Pathologist, Union Health Department and Major R. Turner, S.A.M.C., M.B., Ch.B. Senior Assistant Pathologist, Union Health Department. With a foreword by The Hon. Mr. Justice H. S. van Zyl, Judge-President of the Cape Provincial Division of the Supreme Court of South Africa. Cloth. Pp. 218 with illustrations. Cape Town: Stewart Printing Co. (Pty.) Ltd. 1942.

This is a handbook dealing with problems of medical jurisprudence, or legal medicine, in relation to South African conditions. It is a practical manual rather than a comprehensive book of reference and is based on lectures given at the University of Cape Town. As pointed out in the foreword written by the Judge-President of the Cape Provincial Division of the Supreme Court of South Africa, the pains the authors have taken to enumerate and stress the essentials that should be looked for by a medical practitioner when conducting a post-mortem or other important examination should greatly facilitate and add to the thoroughness of the work of district surgeons in South Africa and others entrusted with any such examination and should enable them to assist the court, if called to give evidence, with insight and assurance. In appendices the authors have reproduced the statutory provisions which are of special importance to medical practitioners. Discussions of the duties of magistrates and district surgeons in relation to medicolegal deaths are included by the authors, and chapters deal with the various classifications of deaths of medicolegal importance, such as deaths from burns, suffocation, strangulation, drowning, poisoning and from regional injuries. A special chapter is devoted to firearm wounds and forensic ballistics. While the book was written primarily for South African consumption, it contains much that will be of interest to readers elsewhere whose intellectual curiosity has been aroused in the broad subject of legal medicine.

Emotions and Memory. By David Rapaport, Ph.D. Head of the Department of Psychology, the Menninger Clinic, Topeka, Kansas. The Menninger Clinic Monograph Series No. 2. Cloth. Price \$3. Pp. 242. Baltimore: Williams & Wilkins Company, 1942.

David Rapaport is a psychologist, not a medical man, who is closely integrated with medical procedures as the result of his connection with the Menninger group of hospitals, where he has had a chance to observe conduct disorders of varying degrees in both children and adults. He is also an expert on the so-called Rorschach technique and is well versed in the whole problem of psychology as it applies to psychopathology. The present volume is an interesting summary of the problem of emotions which has offered conceptual confusion to the psychiatrist and, even after the present book has been read, has not by any means been oversimplified. Nevertheless the book summarizes the literature extensively and the work of psychiatry and psychology on emotions. Such fields are covered as experimental psychology, psychoanalysis, hypnosis, studies of pathologic memory phenomena and direct experimental evidence such as the Rorschach test. The literature referred to in each chapter is at the end of the chapter and there is no comprehensive bibliography at the end of the book. There is an author index and a rather short subject index. The author points out some implications, some of the problems which have been set up, and the meaning of forgetting and recollection in terms of emotion. There is some discussion in the concluding chapter as to the nature of the forgetting process in terms of emotion and there is some integrating in the various fields of psychology. There is no original experimental material, but as a source book in the field of emotion and memory, the integral relationship of which is so important to psychiatrists, it will supply a much needed source of reference.

An Introduction to Group Therapy By S. R. Slavson, Director of Group Therapy, Jewish Board of Guardians, New York. Cloth. Price \$2. Pp. 352. New York: Commonwealth Fund. London: Oxford University Press, 1943.

The treatment of mental disorders by group means has been advanced along many lines recently. The present activity describes the efforts made at a group of schools for the purpose of character education. An excellent discussion tells how groups can be handled for therapeutic purposes, describes technique and processes such as the supervision and the meeting of those carrying out the activity. Then a number of exemplary records are presented followed by a discussion of the selection of clientele from the point of view of types of families accessible, types of children inaccessible and the natural tendencies of grouping within a large group. Such functions of leadership as acceptance or authority, the likelihood of defeat of the therapist by members of the group, authority familiarity and humor are discussed in an interesting fashion. There is a further discussion of the therapeutic process itself and five typical cases are given. The volume ends with a discussion of the variations in group therapy and there are four appendices: a short glossary and a fairly good index. The book is primarily of value to those who have to deal with problem children, particularly those who might be in a juvenile criminal group rather than maladjusted or childhood neuroses. The book is based on the detailed records of seven hundred and fifty children and fifty-five groups which functioned for about two years. The records include follow-up studies of adjustment for those placed in a group with arranged recreational activities. It is a useful adjunct to those who have to deal with this type of child and for the criminal psychopathologist who has a broad view toward therapy, and there should be a number of stimulating leads. It is not a book which needs to be in the general practitioner's library, however.

Behavior and Neurosis: An Experimental Psychoanalytic Approach to Psychobiologic Principles By Jules H. Maceraman, M.D., Assistant Professor of Psychiatry, University of Chicago. Chicago: Chicago University Press, 1943. Pp. 264 with 7 illustrations. Cloth. Price \$3.

The author of this book is a well trained psychiatrist who has had a great deal of experience not only in psychiatry but in psychoanalysis. The present volume is an attempt to give a biogenetic basis for the psychoanalytic interpretation of the neuroses. The author has checked much of his historical material on mental functions as seen in animals in such a way as to point toward his own studies. The processes are carried out with cats. The cats are frustrated in several ways through the feeding technique. There is a summary of the various behavior patterns shown by the animals, and an extensive analysis was made of the conditioned reflex concept of the motivation of behavior and the effect of frustration. A short chapter considers the evaluation of the findings in terms of psychotherapy. An extremely detailed bibliography and an excellent pair of indexes for author and for subject complete the work. The book is suggestive of further procedures and is probably a significant contribution to an experimental verification of psychoanalytic concepts as has thus far been produced.

Tuberculosis As It Comes and Goes By Edward W. Hayes, B.S., M.D., F.A.C.P., Associate Professor of Tuberculosis, College of Medical Surgeons, Los Angeles. Cloth. Price \$2. Pp. 157 with illustrations. Monrovia, California: The Author, 1943.

Although written primarily for patients, this book should be read by physicians everywhere. The first chapter consists of a brief but excellent history of the development of our knowledge of tuberculosis. This is followed by several chapters dealing primarily with the tubercle bacillus. What this organism is, how it infects the body, how the body defends itself and the incidence of infection in various parts of the world are clearly presented. The classification of tuberculous lesions is discussed and illustrated by numerous drawings. Under the subject of diagnosis, the author gives the tuberculin test the first place. This is followed by a ray film inspection of the chest. This is then followed by the various steps necessary to determine whether an x-ray shadow represents tuberculosis or some other disease. Several chapters are devoted to treatment in which the author discusses such subjects as the general care of the

patients, sanatorium vs. home treatment, rest, diet, climate, chemotherapy and the various methods of collapsing the lung. Collapse therapy is illustrated by a large number of drawings. Careful consideration is given to the complications of tuberculosis such as pulmonary hemorrhage and pregnancy. Dr. Hayes has had a large experience in dealing with all phases of tuberculosis. His work as a clinician and educator is widely known. His book should be made available to the public everywhere, as it contains a large volume of authentic and thoroughly dependable information which should be used to great advantage in the entire tuberculosis control movement not only in this country but throughout the world.

Your Arthritis: What You Can Do About It By Alfred E. Phelps, M.D., with an introduction by R. Garfield Snyder, M.D. Cloth. Price \$2. Pp. 192 with illustrations by James MacDonald. New York: William Morrow and Company, 1943.

This small book is one of the best outlines of the subject of arthritis for the public. It was written by a doctor well qualified to present the subject. The introduction is by R. Garfield Snyder, a clinician who devotes nearly all his time and effort to the study and control of arthritis. Snyder says that in the majority of cases arthritis is curable and practically always can be brought under control. Both statements are wide open for discussion. Most clinicians wish these statements were true. The book was written with a twofold purpose: to tell the patient how to cooperate with his doctor in making life as easy and pleasant as possible while under treatment and to help the busy doctor who has little time especially in these days, and help the patient get the most out of life. A few of the chapters discuss the prevalence of arthritis and some of its causes, the effects of different temperaments on treatment, what makes arthritis hurt, the relation between climate and arthritis, areas of infection, when teeth should be pulled or operations performed in treatment of arthritis, when the body rebels, symptoms of the disease, gouty arthritis, the effect of faulty posture and gait, various effective methods for treatment of arthritis now in use, methods of preventing arthritis, deformities and relapses, the myth of 'acid system' factors, necessary in planning a reducing diet and how the patient can cooperate with his doctor to make life pleasanter for himself and to speed effective treatment.

A Manual of Pulmonary Tuberculosis and an Atlas of Thoracic Roentgenology By David O. Lindberg, M.D., F.A.C.P., Director of Roentgenology, State Sanatorium, Oakdale, Iowa. Cloth. Price \$6.50. Pp. 233 with 189 illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

This book is a valuable contribution to the literature on diseases of the chest. In part I, which consists of seventy-two pages, the author has condensed all the important information that the physician needs in the diagnosis, treatment and control of tuberculosis. For many years Dr. Lindberg has devoted a large amount of time to x-ray studies of the various diseases of the chest. In fact, after studying in Brazil, he introduced the 35 millimeter film in the United States. All the diagnostic, therapeutic and preventive procedures in part I are well standardized. With each of them the author has had wide experience. Part II consists of excellent reproductions of 145 roentgenograms. These have been selected with great care and represent practically all the diseases of the chest which the physician encounters in this country. In arriving at final diagnoses in each case represented, the author did not depend entirely on the roentgenograms but employed all the other procedures necessary to make accurate diagnoses. This book should be made available to all physicians. It should also find an important place in the teaching of diseases of the chest to medical students.

Malaria Quiz for Young Americans Federal Security Agency U. S. Public Health Service, Community Health Series No. 4. Paper. Pp. 2, with illustrations. Washington, D. C.: Upt. of Doc. Government Printing Office, 1943.

This is one of the most easily readable, wholly educational pamphlets about a single disease thus far made available. It is highly recommended to any one who wants to know about malaria.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

Rh FACTOR AND ERYTHROBLASTOSIS

To the Editor—Recent articles on erythroblastosis fetalis fail to answer the following questions: 1. What, if any, are the chances of an Rh positive father and an Rh negative mother becoming the parents of an Rh negative infant? Have specific instances been reported? 2. What, if any, are the chances of an Rh negative mother who has previously given birth to an infant suffering from erythroblastosis bearing a normal Rh positive offspring, that is, one showing no stigmas of this disease?

M D, Minnesota

To the Editor—I should like some information concerning the Rh factor, its significance, interpretation and importance in regard to obstetrics. I have a patient who gave birth to an eight month stillborn infant. Examination of both parents revealed absolutely negative findings except for the Rh factor, where one was positive and the other negative. Please explain these findings and advise whether another pregnancy should be undertaken. Is there any therapy that could be undertaken to make this pair the same?

M D, New York

ANSWER—1. An Rh negative mother and an Rh positive father can have Rh negative children provided the father is heterozygous for the Rh factor. It has been demonstrated (Landsteiner, Karl, and Wiener, A. S. Studies on an Agglutininogen [Rh] in Human Blood Reacting with Anti-Rhesus Sera and with Human Isoantibodies, *J. Exper. Med.* 74: 309 [Oct.] 1941; Wiener, A. S. Blood Groups and Transfusion, ed. 3, Springfield, Ill. C. C. Thomas, 1943) that the Rh factor is transmitted as a mendelian dominant by a pair of allelic genes, *Rh* and *rh*. Therefore Rh negative individuals are all homozygous, genotype *rrhh*, while Rh positive individuals can be either homozygous, genotype *RhRh*, or heterozygous *Rh rh*. It is evident that if the Rh positive parent in the mating Rh positive \times Rh negative is homozygous, then all the children will be Rh positive, while if the Rh positive parent is heterozygous, half of the children will be Rh positive and half will be Rh negative. Ample instances of this can be found in the references cited.

2. If an Rh negative mother has previously had a child with erythroblastosis, the chances are that every future Rh positive child will also have the disease, in fact, usually in progressively severer form. There is, however, always the remote possibility that the mother may suddenly become spontaneously desensitized, just as hay fever sufferers occasionally recover from their disease without treatment.

3. In the case cited in the second letter, it is important to know which of the two parents was Rh negative and which was Rh positive. If it was the mother who was Rh negative and the father Rh positive, the chances are that the eight month stillborn child had erythroblastosis, provided other causes of death, such as syphilis, torsion of the umbilical cord and asphyxia, are excluded. Once an Rh negative mother has had an erythroblastic baby, all future Rh positive children are almost certain to have the disease whereas Rh negative babies will be spared (Levine, Philip, Burnham, Lyman, Katzin, E. M., and Vogel, Peter. The Role of Iso-Immunitization in the Pathogenesis of Erythroblastosis Fetalis, *Am. J. Obst. & Gynec.* 62: 925 [Dec.] 1941). As pointed out, the chance that future children will be Rh positive is either 50 or 100 per cent, depending on whether the Rh positive parent is heterozygous or homozygous.

Before offering any opinion concerning the outlook of future pregnancies, it would first be necessary to repeat the Rh tests in order to exclude the possibility of error in technique. Such errors are not uncommon on account of the delicacy of the tests. If the retests show that the mother is Rh negative and the father Rh positive, the prognosis should be guarded while if the mother proves to be Rh positive the chance for a normal baby in future pregnancies is usually good. If the mother decides that, despite the fact that she is Rh negative she wants to undertake another pregnancy, she must be made to realize that she does so at the risk of having another stillbirth or infant with erythroblastosis fetalis. If the baby is born alive there is a good chance of saving it by judicious transfusions of group O Rh negative blood. There is no therapy which can change the Rh type of any individual, since the type is constitutional and remains constant throughout life.

USE OF TERMS GRAVIDA AND PARA

To the Editor—Recently at our hospital we have had several "heated" discussions among the interns and obstetric staff as to the definition and practical usage of certain obstetric terms. The main substance of the argument was in the proper usage of Para I, Para II, Para III, and so on, with its relationship to primipara, multipara, primigravida, multigravida and other similar terms. It has been the practice on our obstetric sheets to list at the top of the history sheet of a woman who is coming into the hospital to have her first child, this being her first pregnancy, Gravida I, Para 0. Therefore, on her next admission, being admitted in labor, about to have her second child, her admission record would read Gravida II, Para I. There has been no misunderstanding of the term gravida, but several of the men feel that the classification as noted, even though carried out at several surrounding institutions, is wrong and that, since this woman coming in is known universally as a primipara, her chart should read Gravida I, Para I even before the birth of her child. When I was an intern we argued about the same definitions and usage of the terms, and it seems that with the various definitions given in the dictionary it is an endless argument, the dictionary agreeing with both points of view. We should appreciate it greatly if you would help us clarify this subject by advising us of the accepted definitions and the practice and procedures that are carried out in various institutions throughout the country relative to this subject.

M D, Pennsylvania

ANSWER—The terms gravida and para have been subjected to various interpretations. The following definitions have found wide acceptance.

Gravida refers to a pregnancy, regardless of its duration. Parity refers to pregnancies that have continued to the period of viability. A patient is Gravida I during her first pregnancy. She becomes Para I when she delivers a fetus which has been viable whether or not the child is actually dead or alive at birth. During the second pregnancy she is listed as Gravida II, Para I. If she had two abortions and then becomes pregnant, she would be Gravida III, Para 0. The period of viability is reached at the end of twenty-eight weeks' gestation.

To be consistent, a patient during her first pregnancy is a primigravida and during her second and subsequent gestations a multigravida. She is not a multipara unless she has had at least two pregnancies that reached the period of viability. The terms concern themselves with the pregnancy and not with the fetus, for a woman who has delivered twins at the end of her first pregnancy is still Gravida I, Para I.

DERMATITIS AMONG CANNERS

To the Editor—We have a corn canning company in our village, and the manager has approached me for a solution to one of his problems. In the past most of the workers there have worn rubber gloves as a protection from a contact dermatitis which they refer to as "corn itch." I understand that this has been common wherever corn is canned, so I imagine that it has received attention in the literature. Is there any other practicable method known than wearing rubber gloves which will afford suitable protection for the workers? If not, do you know if priorities for the purchase of rubber gloves are obtainable for such industries?

C. T. Bergen, M.D., Bricelyn, Minn.

ANSWER—Dermatitis among fruit and vegetable canners is quite common. The types of dermatitis in the canning industry are much alike regardless of the material that is being canned.

The best protection against dermatitis in the canning industry is the wearing of rubber gloves, impervious sleeves and impervious aprons. Since the canning of fruit and vegetables is an industry essential to the war effort, priorities for the purchase of rubber gloves to protect workers can be obtained.

The impervious sleeves and aprons are not on priorities. They can be purchased from the West Disinfecting Company, Long Island City, N. Y., the Milburn Company, Detroit, and Don-Ed Fabrics, Inc., New York.

PHYSICAL EFFICIENCY AND TOBACCO SMOKING

To the Editor—In *The Journal*, July 17, 1943, page 839, the question is asked "Is there any scientific basis for the popular belief that smoking causes shortwindedness?" I have never been in agreement with the statement that the shortness of breath appears to be due to the effect of nicotine on the heart and circulation, nor am I in agreement that the pain on exertion in heavy smokers is due to the coronary contraction resulting from the action of nicotine. It is my personal belief, formed after many years of study of so-called tobacco shortwindedness, that it is due to the habit of "breathing shallow" during extended periods of smoking. That is, the smoker spends a good deal of his time in smoking and therefore gets into the habit of breathing shallow with a narrow respiratory excursion. When the time comes for a wider respiratory excursion because of increased oxygen requirements, the embarrassment is due to calling into play additional lung and muscle tissue that has not previously been functioning. If the smoker who experiences shortwindedness will practice deep breathing when he is not smoking he will not have shortwindedness. This to me is a clear indication that shortwindedness is not due to nicotine per se but is due to habitual shallow breathing.

SULFAMERAZINE

CLINICAL EVALUATION IN 116 CASES

WENDELL H. HALL, MD
AND

WESLEY W. SPINK, MD
MINNEAPOLIS

Investigations have continued in a search for more therapeutically effective sulfonamides which at the same time provoke less toxic manifestations. In our experience at the University of Minnesota Hospitals sulfadiazine has proved to be less toxic than sulfathiazole, sulfapyridine and sulfanilamide. Nevertheless it has been found that renal complications are not uncommonly associated with sulfadiazine therapy. For this reason the therapeutic possibilities of the monomethyl derivative of sulfadiazine were investigated. This report presents the results that have been obtained in the treatment of 116 patients with sulfamerazine and its sodium salt.

Sulfamerazine, the monomethyl derivative of sulfadiazine, is 2-sulfanilamido-4-methylpyrimidine. The dimethyl derivative of sulfadiazine is known as sulfamethazine and is 2-sulfanilamido-4,6-dimethylpyrimidine. Sulfamerazine was first described by Roblin and his associates.¹ They found that sulfamerazine was two and one half times as soluble in water as sulfadiazine. Its acetylated form had almost the same solubility as free sulfamerazine in water and was almost twice as soluble in water as acetylated sulfadiazine. Roblin and his associates² also prepared sulfamethazine and observed that it was two and one half times as soluble in water as sulfamerazine. Sulfamerazine and sulfamethazine were also prepared by Sprague, Kissinger and Lincoln.³ Sulfamethazine has been synthesized by Caldwell, Kornfeld and Donnell.⁴ They found that its water solubility at 29 C was twice that reported by Sprague and his associates³ in water at 37 C.

Roblin and his group¹ observed that higher maximum blood levels could be established in white mice with sulfamerazine than with identical doses of sulfadiazine.

The sulfamerazine was generously supplied by Sharp and Dohme Inc.

From the Division of Internal Medicine, University of Minnesota Hospitals and Medical School.

This study was successfully completed because of the cooperation of the staff members in the various departments at the University of Minnesota Hospitals. The sulfamerazine concentrations were carried out under the direction of Dr. G. T. Evans, director of the laboratories. Mrs. Ruth F. Curry, in charge of the bacteriology laboratory, was responsible for most of the bacteriologic data.

4. Caldwell W. T., Kornfeld E. C. and Donnell C. K. Substituted 2-Sulfanilamido-pyrimidines. *J. Am. Chem. Soc.* 63: 2168 (Aug.) 1941.

With equivalent doses of sulfamethazine they obtained the same maximum blood levels as with sulfamerazine.²

Welch and his associates⁵ studied the pharmacology and toxicology of sulfamerazine in laboratory animals and in man. The minimum lethal dose in white mice was reported to be about the same as for sulfadiazine. In chronic toxicity experiments with dogs and monkeys no tissue changes were found unless the average eight hour concentration in the blood exceeded 30 mg per hundred cubic centimeters. The toxic effects were in the most part dependent on precipitation of the drug in the renal tubules, pelvis or ureters. Free sulfamerazine was found to be more soluble in urine than free sulfadiazine, and acetylated sulfamerazine was more soluble in urine than acetylated sulfadiazine. The solubility of all these compounds in urine was greatly increased when the p_H of the urine was raised from 6.5 to 7.5. Sulfamerazine was more rapidly and more completely absorbed from the gastrointestinal tract than sulfadiazine. In comparison with sulfadiazine, sulfamerazine was also more slowly excreted in the urine and therefore appeared in lower concentrations. The degree of acetylation was the same as with sulfadiazine. The production of neuropathologic changes in chickens was no greater with sulfamerazine than with sulfadiazine. When sulfamerazine was administered to human subjects it appeared that adequate blood levels could be quickly attained without the necessity of giving the sodium salt intravenously and that such levels could be maintained by giving only one or two doses by mouth daily.

Goodwin, Peterson and Finland⁶ reported that after 5 Gm of sulfamerazine was given orally to 3 men the blood levels rose more rapidly and higher levels were reached and were sustained longer than after an equal dose of sulfadiazine. Most of the drug in the blood was found to be in the plasma. More sulfamerazine was excreted in the urine than sulfadiazine, and more of the sulfamerazine in the urine was in the conjugated form.

Roblin and his associates¹ concluded that sulfamerazine was more effective than sulfanilamide, sulfapyridine and sulfathiazole in white mice having infections due to streptococci, staphylococci and pneumococci. They believed that the superiority of sulfamerazine was due to the higher blood levels obtained with this compound. Goodwin, Peterson and Finland⁶ reported that sulfamerazine was bacteriostatic in vitro against type III pneumococci in low concentrations of the free drug.

As yet no reports are available concerning the value of sulfamerazine in the treatment of human infections. McCartney and his associates⁷ reported on the pharmacology and clinical trials of sulfamethazine in 88 human infections. They found that sulfamethazine was effective against infections due to pneumococci, meningococci and gonococci. They reported no serious toxic complications. Jennings and Patterson⁸ found that sulfamethazine was effective in 27 children when it was used against infections due to pneumococci and meningococci. No serious toxic reactions were encountered.

MATERIALS AND METHODS

The various types of clinical conditions in 116 patients treated with sulfamerazine or its sodium salt are presented in table 1. Of the 116 patients, 15 were children under 1 year of age. In every case, attempts were made to isolate the infectious agent responsible for the disease.

The 47 patients with pneumonia made up the largest group treated. The sputum when available was examined in all instances, and if pneumococci were present the Neufeld method of typing was used. Blood cul-

tures were obtained from all patients with pneumonia before chemotherapy was instituted. Data were obtained from the patients on age, time of onset of illness, extent of the pulmonary involvement, complications, x-ray films of the chest during therapy, frequent blood sulfamerazine levels and effect of the therapy on the clinical course, temperature and blood morphology. The oral dose of sulfamerazine in the treatment of adults and older children consisted of an initial dose of from 3 to 4 Gm followed by 1 Gm every six hours. This dosage was maintained until the temperature had remained normal for forty-eight hours and then was reduced to 0.5 to 1 Gm every eight hours. The drug was discontinued on the fifth to the seventh day. In infants and smaller children the initial dose was 0.05 Gm per pound of body weight (not over 4 Gm) and the maintenance dose was 0.05 Gm daily per pound of body weight given in divided doses until the temperature returned to normal. Then the dose was gradually reduced, and the drug was discontinued on the fifth to the seventh day. We did not administer an alkali with the sulfamerazine to these patients. In 1 instance type specific antipneumococcus rabbit serum was administered in conjunction with the sulfamerazine. To

patients who were nauseated or extremely toxic, the initial dose was given intravenously in the form of the sodium salt. Four Gm of this drug was given as a 5 per cent solution in isotonic solution of sodium chloride. In all instances the patients were then maintained on oral therapy.

Eight patients with acute bronchitis apparently due to pneumococci were treated with sulfamerazine. There was no evidence of involvement of the lung parenchyma in any of these patients. One of these patients had a bacteremia. The dosage of sulfamerazine was the same as used for patients with pneumonia.

Eleven patients with staphylococcal sepsis were given sulfamerazine. Two patients had a bacteremia, 1 in association with osteomyelitis and thyroiditis, the other related to multiple subcutaneous abscesses. The remaining patients were treated because of osteomyelitis, postoperative wound infections, infected burns, carbuncles, decubitus ulcers and perirectal abscess. The dosage employed was the same as with pneumonia but in most cases was given over a longer period of time. Surgical drainage of the abscesses was performed when fluctuation was present.

Two patients with influenzal meningitis (type B), 3 with meningococcal meningitis and 2 with streptococcal meningitis were treated with sulfamerazine. An attempt was made to maintain a blood level of free sulfamerazine between 15 and 20 mg per hundred cubic centimeters. In some of the cases oral therapy was supplemented by intravenous therapy. Type specific serum was given intravenously to the patients with influenzal meningitis. Type specific serum was given intravenously to 1 patient with meningococcal meningitis.

Thirty-one patients were treated for streptococcal sepsis with sulfamerazine. Twenty-three of these patients had acute tonsillitis or pharyngitis due to hemolytic streptococci. These patients were given 3 Gm initially and then 1 Gm every eight hours for forty-eight hours. The other infections included cellulitis, otitis media, sinusitis, scarlet fever and 1 instance of septicemia due to beta hemolytic streptococci.

The concentration of the free sulfamerazine in the blood was determined by the method of Bratton and Marshall.⁹ In the patients with meningitis simultaneous determinations were made on the blood and spinal fluid.

PNEUMONIA AND ACUTE BRONCHITIS

Table 2 presents the results of therapy with sulfamerazine in 55 patients having lobar pneumonia, atypical pneumonia or acute bronchitis. There were 32 patients with lobar pneumonia or bronchiopneumonia, all of whose sputums contained micro-organisms consistent morphologically with pneumococci. The pneumococci were successfully typed in 19 of the 32 patients. Three of these patients died. One of the patients had a type I pneumococcus pneumonia and bacteremia. This person was a chronic alcoholic addict with delirium tremens as a complication and had consolidation of the right middle and lower lobes. There were type I pneumococci in the blood culture. In addition to receiving sulfamerazine, he was given type specific antipneumococcus rabbit serum intravenously. After the slow injection of 60,000 units of serum the patient had a convulsion, became pulseless and died. The

urine output increased, but death ensued. Autopsy revealed a carcinoma of the stomach, and the entire right lung was collapsed and necrotic. One child with lobar pneumonia due to type XXIX pneumococci recovered but died later of Schüller-Christian disease. The postmortem examination revealed no evidence of pneumonia.

One patient with thyrototoxicosis developed a lobar pneumonia due to type XI pneumococci after thyroidectomy. Therapy with sulfadiazine was instituted but he developed severe jaundice and delirium. Sulfamerazine was then administered and his jaundice and delirium cleared rapidly. His improvement was striking. Of the 2 patients with lobar pneumonia due to type III pneumococci, 1 had had a bilateral otitis media which improved rapidly following chemotherapy. In both cases the pneumonia responded quickly to sulfamerazine therapy, although in 1 there were frequent recurrences because of an underlying bronchiectasis with cavitation.

The following case is presented in detail because it illustrates well the response seen in the majority of cases of pneumococcal lobar pneumonia.

CASE 1—S. K., a man aged 23, a student, entered the University Hospitals after an illness of three days duration characterized by chills, fever, cough and sweats. He had had pain in his right upper chest and blood streaked sputum for two days. He had vomited several times. He was dyspneic and moderately cyanotic. Decreased resonance, bronchial breathing, moist rales and increased vocal fremitus were found over the apex of the right lung. X-ray examination of his chest revealed consolidation of the entire right upper lobe. Numerous type I pneumococci were found in his sputum but the blood culture remained sterile. The patient showed an excellent response to sulfamerazine. His temperature fell rapidly and he felt subjectively improved. The physical findings in his chest rapidly disappeared. He was discharged eight days after his admission to the hospital.

Attempts to type pneumococci in 13 of the patients with lobar pneumonia or bronchopneumonia were unsuccessful by both direct and indirect methods. All the 13 patients recovered and responded satisfactorily to sulfamerazine therapy. One of these patients had a bacteremia due to unidentified gram negative bacilli and gram positive diplococci, 1 developed a pleural effusion and another had a transient auricular fibrillation.

One patient with hemolytic streptococcus pneumonia recovered following therapy with sulfamerazine. Two patients with bronchopneumonia had numerous colonies of nonhemolytic streptococcus in the sputum and responded satisfactorily following the administration of sulfamerazine.

Twelve patients with so-called atypical pneumonia of doubtful etiology were treated. As was to be anticipated the therapeutic response was variable, and in most instances the drug did not appear to have any beneficial effect on the clinical course. One of the 12 patients died from cardiac failure. One patient with an otitis media due to *Staphylococcus albus* responded in excellent fashion. Both the otitis media and the pneumonia rapidly subsided coincident with the use of sulfamerazine.

During the past winter 8 patients were seen who had a pneumococcal bronchitis. Physical examination and x-ray films of the chest failed to demonstrate any involvement of the lung parenchyma. All these patients had fever, cough, bloody or purulent sputum and chest pain. All were treated with sulfamerazine with satisfactory results. They were given the same dose as

Chart 1—Result of sulfamerazine therapy in case of type I pneumococcus pneumonia

used for patients with frank signs of pneumonia. No toxic reactions were observed. One of these patients had a type XII pneumococcus bacteremia with 40 colonies per cubic centimeter of blood. Following therapy with sulfamerazine he recovered readily from his bronchitis and his blood stream was quickly rendered sterile. However, after a lapse of several days he developed

an abscess in the right inguinal region from which type XII pneumococci were recovered. Surgical incision and drainage was necessary. Another patient with an acute pneumococcic sinusitis and bronchitis due to type VIII organisms responded well in all respects.

In general, the effect of sulfamerazine on the clinical course of pneumonia resembled that which we have encountered with sulfadiazine. In most instances of lobar pneumonia the temperature curves approached normal within twenty-four to forty-eight hours. The drug was well tolerated by all the patients. In some cases in which a toxic reaction followed sulfadiazine therapy, sulfamerazine was well tolerated.

Chart 2—Sulfamerazine therapy of infant aged 2 months with type B influenza bacillus meningitis

STAPHYLOCOCCIC SEPSIS

Staphylococcic infections were treated in 11 patients, 2 of whom had a bacteremia. The 9 patients without demonstrable blood stream invasion had localized lesions such as furuncles, carbuncles, postoperative wound infections, osteomyelitis, infected burns and decubitus ulcers. When combined with adequate surgical drainage, satisfactory results were obtained with the majority of these patients. However, at the present time we feel that sulfathiazole is the sulfonamide of choice for staphylococcic infections. In all instances the sulfamerazine was given by mouth. The drug was not applied locally.

One of the patients with bacteremia was hospitalized because of leukemia. Several subcutaneous abscesses developed and were associated with chills, a septic

type of fever and a bacteremia. Sulfamerazine was given orally in the same dosage used in the treatment of pneumonia. The blood culture became sterile and the temperature returned to normal. The subcutaneous abscesses receded very slowly without surgical drainage. The other patient with a staphylococcic bacteremia also had an acute osteomyelitis. The patient was somewhat less febrile while taking sulfamerazine, but the bacteremia persisted and she developed an acute thyroiditis.

INFLUENZAL MENINGITIS

Two infants with influenzal meningitis (type B) were treated successfully with sulfamerazine. The first infant was a girl aged 11 months under the care of Dr. Erling Platou. Therapy was started with sulfadiazine, and type specific rabbit serum was given intravenously. A good clinical response was obtained, but after six days of therapy she developed oliguria. She was then given sulfamerazine. Her urine output increased and she recovered.

The following is a summary of the clinical course in the second case.

CASE 2—R. B., a boy aged 2 months, entered the University Hospitals in the service of Dr. Irvine McQuarrie. He had become irritable and cyanotic two days before admission to the hospital. Some opisthotonos had been noted and his temperature had reached 104°F. He had had an upper respiratory infection one and one-half weeks before entry, which had subsided promptly. The child had a moderate opisthotonos on admission to the hospital. He was dehydrated. His neck was rigid and his respirations were irregular. The anterior fontanel was bulging. The ears, throat and lungs were normal. The optic disks were edematous. There was a systolic murmur at the apex of the heart. The abdomen was normal. The upper extremities were flexed and rigid. Turbid spinal fluid was removed under a pressure of 8 mm of mercury. Gram negative pleomorphic bacilli were seen in the spinal fluid on stained smears, and cultures yielded type B influenza bacilli. The child was given sulfamerazine, parenteral fluids, blood transfusions, type specific serum and oxygen. For three days he had clonic convulsions. After eight days his clinical condition appeared improved, and repeated spinal fluid examinations revealed a drop in the leukocyte count. On the seventeenth hospital day the spinal fluid sugar exceeded 20 mg per hundred cubic centimeters. He became afebrile and improved gradually. He gained 1 Kg in weight while in the hospital. No definite evidence of residual cerebral damage was found. Although the infant vomited frequently during the early part of his hospital stay, there was no evidence that this was induced by sulfamerazine.

MENINGOCOCCIC MENINGITIS

Three patients with meningococcic meningitis were treated with sulfamerazine. All these patients recovered. One, a male student aged 18, was treated at the Student's Health Service under the care of Dr. Ruth Boynton and Dr. C. A. McKinlay. He was given sulfadiazine initially and had a favorable response. On the eighth day of sulfadiazine therapy he developed crystalluria, right flank pain and hematuria. He was then given sulfamerazine. The renal symptoms subsided promptly and he recovered.

The second patient, a man aged 51, received only sulfamerazine and recovered after a prolonged illness. Vomiting occurred frequently during the early part of his illness, but this subsided while he was still receiving sulfamerazine. An indwelling catheter led to a urinary tract infection after the sulfamerazine was discontinued. This infection cleared up after a brief course of sulfathiazole.

The third case was of interest from several aspects and is presented in more detail

CASE 3—M S a woman aged 21, was admitted to the University Hospitals because of recurrent headaches and convulsions of five years duration. The neurologic examination was essentially negative, and a diagnostic lumbar puncture revealed normal spinal fluid. She was discharged but returned to the hospital six days later. She stated that she had had a severe and persistent headache since the lumbar puncture. Four days before her second admission to the hospital she had noted the onset of fever and back pain. One day later her neck became stiff and deafness and tinnitus appeared in her left ear. She appeared dehydrated and very ill. A rotatory nystagmus was present. Her hearing was reduced in her left ear and her neck was rigid. The heart, lungs and abdomen were normal. Kernig's sign was positive bilaterally. The initial lumbar puncture revealed cloudy spinal fluid under a pressure of 20 mm of mercury. Meningococci were found in the spinal fluid by stained smears and culture. She was given 5 Gm of sodium sulfamerazine intravenously initially, and this was followed by 1 Gm of sulfamerazine orally every three hours. Her fever subsided slowly by itself. Her headache persisted for several days and was associated with nausea and vomiting. These symptoms could not be correlated with the sulfamerazine therapy. Her neck rigidity subsided and the nausea vomiting and headache gradually disappeared. Although she made an excellent recovery a reduction of hearing remained in her left ear.

STREPTOCOCCIC MENINGITIS

There were 2 patients in this series who had meningitis which appeared to be due to streptococci. The first patient was a boy aged 10 who presented the picture of an acute meningitis associated with a transient generalized rash. Although no organisms could be isolated from his spinal fluid by smears or cultures, hemolytic streptococci were cultured from his nose and throat. He had an excellent clinical response with sulfamerazine therapy. After thirteen days of chemotherapy his leukocyte count dropped to 2,400 with 37 per cent neutrophils, 56 per cent lymphocytes, 6 per cent monocytes and 1 per cent eosinophils. The sulfamerazine was discontinued, and his leukocyte count promptly rose to 7,400.

The other patient developed an acute meningitis following an operation for a ruptured appendix. The spinal fluid was sterile on culture. His condition gradually grew worse in spite of sulfamerazine therapy, and he died. The postmortem examination revealed a purulent meningitis with abscesses in the brain and liver. Gamma streptococci were cultured from the brain, spinal fluid, liver and spleen.

STREPTOCOCCIC SEPSIS

The second largest group of patients treated with sulfamerazine had infections due to streptococci. One of these patients had a bacteremia due to beta hemolytic streptococci. There were 600 colonies per cubic centimeter of blood. This infection developed as a result of an infected decubitus ulcer. The patient was given sodium sulfamerazine subcutaneously and the blood cultures became sterile for several days. Hemolytic streptococci again appeared in the blood cultures and the patient died after a prolonged illness. Permission for an autopsy was refused.

One patient with bilateral otitis media, and another with acute sinusitis both due to beta hemolytic streptococci were successfully treated with the drug. One man aged 87 with an extensive cellulitis and lymphangitis due to a hemolytic streptococcus infection of one foot recovered following therapy with sulfamerazine.

Twenty-three patients with acute tonsillitis and pharyngitis due to hemolytic streptococci were treated with sulfamerazine at the Student's Health Service. Most of these patients were given 3 Gm initially followed by 1 Gm every six hours for forty-eight hours. The clinical response was excellent in most of these cases. However, several of these patients continued to have hemolytic streptococci in their throats and had subsequent throat infections after a short interval of time.

Four patients with scarlet fever were given sulfamerazine. One of them was also given 90,000 units of streptococcus antitoxin intramuscularly. All of them had hemolytic streptococci in their throats. Following

Chart 3—Result of sulfamerazine therapy in case of meningococcal meningitis

therapy with sulfamerazine the fever subsided rapidly, the skin rash diminished within twelve to twenty-four hours and the patients felt subjectively improved. No visceral complications were encountered in any of these patients, and no toxic manifestations occurred as a result of chemotherapy. Repeated throat cultures however, revealed that in some instances streptococci persisted in their throats. The following case illustrates these points well.

CASE 4—B G a man aged 22 a student had a backache, nausea, headache and fever for one day. He had a rash for twelve hours. He did not appear extremely ill. His pharynx was decidedly injected and his cervical nodes were enlarged. His tongue was red and there was a circumoral pallor. There was an erythematous rash on his abdomen, chest, arm- and legs. Soon after his admission to the hospital he had a chill and a fever up to 103.8 F. Streptococci were cultured from his throat. His response to sulfamerazine was excellent. His fever subsided promptly, his rash disappeared within twelve

hours and he felt well. No evidence of cardiac or renal complications was found. However, a throat culture revealed beta hemolytic streptococci at the conclusion of the sulfamerazine therapy.

MISCELLANEOUS INJECTIONS

Several infections of miscellaneous types were treated. Three patients with chronic brucellosis, including 1 patient with a brucella spondylitis, were given

Chart 4—Sulfamerazine therapy in scarlet fever

sulfamerazine. The patient with the spondylitis and 1 patient without a localized lesion responded moderately well, both became afebrile and felt subjectively improved. The third patient showed no benefit. Two patients with urinary tract infections were treated. Both infections were due to hemolytic streptococci and responded satisfactorily. One infant was treated because of clinical evidence of meningitis developing after the surgical removal of a lumbar myelomeningocele. The spinal fluid was sterile and, although the infant recovered, the value of chemotherapy could not be assessed. One patient with abdominal and pulmonary actinomycosis was given sulfamerazine without benefit.

One of the most interesting patients was a middle-aged housewife who had a lobar pneumonia which was controlled after two courses of sulfadiazine. She then developed an acute endocarditis, and type I pneumococci were cultured from her blood. Sulfamerazine was given to her but she died after a stormy course. Autopsy revealed no evidence of pneumonia, but there was a large vegetation on the mitral valve.

Three children with acute laryngotracheobronchitis were treated. Staphylococci and nonhemolytic streptococci were found in their throat cultures. Two of these patients recovered rapidly, the third child gave no response to chemotherapy, and recovery was prolonged. One patient with infectious mononucleosis improved coincident with the use of sulfamerazine.

ABSORPTION AND DISTRIBUTION

Our studies have indicated that sulfamerazine when given orally will lead to a higher blood level in a shorter interval of time than equal doses of sulfadiazine. Adequate blood levels could be maintained with sulfamerazine given at longer intervals than with sulfadiazine. The amount of the sulfamerazine appearing in the urine or feces was not quantitated in any of the

patients. When the sodium salt of sulfamerazine was given intravenously, higher blood levels were attained in a shorter time than with equal doses of sulfamerazine given by mouth or sodium sulfamerazine given subcutaneously. In a few instances some difficulty was experienced in maintaining adequate blood levels of free sulfamerazine even with the aid of intravenous injections of sodium sulfamerazine. This appeared to be accounted for in part by excessive conjugation of the drug. The amount of the conjugated drug in the blood was not determined routinely.

In several cases the amounts of the free sulfamerazine in the blood and spinal fluid were determined simultaneously. The amount of free sulfamerazine in the spinal fluid averaged 50 to 60 per cent of the amount in the blood.

TOXICITY

The toxic manifestations encountered in the treatment of 116 patients with sulfamerazine and its sodium salt are given in table 3. The most frequent evidence of toxicity was nausea and vomiting. Although this occurred in 5 cases, in most instances we were unable to attribute it definitely to the sulfamerazine. The drug was discontinued in only 1 of these cases because of this complication. In 3 cases secondary fever developed which appeared to be due to sulfamerazine, in 2 of these a rash was associated with the fever. The skin eruption was maculopapular in type and was scattered over the entire trunk and extremities. The fever and rash subsided promptly when the drug was discontinued. In 1 child a transient leukopenia and granulocytopenia occurred.

Because of its increased solubility in urine and slower rate of excretion it was hoped that the occurrence of renal complications would be eliminated by the use of sulfamerazine in the place of sulfadiazine. Two of the patients developed back pain, hematuria, crystalluria and reduced urine output when sulfamerazine was given orally. The first patient was treated because of an atypical pneumonia. He had a duodenal ulcer and was nauseated, consequently his fluid intake was low. After receiving 24 Gm of sulfamerazine by mouth he developed left flank pain, microscopic hematuria, crystalluria and oliguria. He was given parenteral fluids, and therapy with the drug was continued. All his symptoms disappeared promptly. The second patient had

TABLE 3—Toxic Manifestations Encountered in a Group of 116 Patients Treated with Sulfamerazine

Manifestation	No. of Patients
Nausea and vomiting	5
Drug fever	3
Dermatitis	2
Leukopenia and granulopenia	1
Gross hematuria and anuria	1
Oliguria	1

a fluid intake which seemed adequate, but she developed bilateral flank pain, gross hematuria, crystalluria and anuria after she had received 17 Gm of sulfamerazine orally. Cystoscopy was performed and the lower ends of both ureters were found to be occluded by large crystals. Ureteral catheters were left in place, and she was given intravenous sodium bicarbonate solution to insure an alkaline urine. Following this procedure a flow of urine was reestablished. Her urine output was maintained over 3,000 cc a day by forcing fluids parenterally. She was discharged from the hospital six days later without any evidence of renal damage.

It is important to point out that this patient also received ammonium chloride for the treatment of an acute bronchitis. The p_H of her urine was found to be 4.6. It is not unlikely that the highly acid urine was a major factor in causing a precipitation of crystals along the urinary tract.

No evidence of peripheral neuritis or other neuro-pathologic disturbance was encountered in any of our patients which was attributed to sulfamerazine. This is in distinct contrast to the earlier experience of others with sulfamethylthiazole.

COMMENT

During the treatment of 116 patients having a variety of infections an attempt has been made to compare sulfamerazine with sulfadiazine with respect to its pharmacology, therapeutic effectiveness and toxicity. Adequate blood concentrations can be maintained with smaller doses of sulfamerazine than with sulfadiazine. Because sulfamerazine is retained in the body for a longer period of time than sulfadiazine, doses of the former may be given at less frequent intervals. Sulfamerazine appears to be just as effective in the therapy of pneumococcal pneumonia as sulfadiazine. Sulfamerazine usually caused a more abrupt fall in temperature than occurred with sulfadiazine. Sulfamerazine also appeared to be just as effective as sulfadiazine or sulfapyridine in the treatment of meningitis due to type B influenza bacillus or the meningococcus. Infections due to hemolytic streptococci responded quite satisfactorily to sulfamerazine and in this respect the results were similar to those obtained with sulfadiazine. Sulfathiazole is more effective than either sulfamerazine or sulfadiazine in staphylococcal infections. Toxic reactions due to sulfamerazine were no more frequently encountered than with sulfadiazine. Sulfamerazine provoked fewer reactions than we had previously encountered with sulfathiazole, sulfapyridine or sulfanilamide. Although sulfamerazine and its acetylated form are more soluble in urine than the comparable forms of sulfadiazine, two of the patients developed renal complications due to precipitation of the drug in the form of crystals within the urinary tract.

Recent investigations would indicate that crystalluria due to sulfadiazine may be prevented, or at least reduced by administering sufficient quantities of an alkali so that the p_H of the urine is maintained at 7.5 or higher.¹⁰ To achieve such an alkaline urine when therapeutic doses of sulfadiazine are being utilized, it has been recommended that from 10 to 20 Gm of sodium bicarbonate should be administered in divided doses every twenty-four hours. As a result of a group of preliminary observations, we are in agreement with the foregoing recommendation. It would also appear that alkalinization is a valuable prophylactic procedure for patients receiving sulfamerazine. This is well illustrated in the following example.

A woman aged 33 at the University Hospitals had subacute bacterial endocarditis due to streptococci of the viridans group. Sulfonamide therapy had failed to clear the blood stream of bacteria. It was decided to give a large dose of sodium sulfamerazine in an attempt to control the infection. She was

given 3 Gm of sodium bicarbonate five times a day, and the twenty-four hour fluid intake was maintained around 5 liters. Twenty-five Gm of sodium sulfamerazine was given intravenously. The twenty-four hour fluid intake on this day was 5300 cc and the urinary output was 1,700 cc. The following twenty-four hour intake of fluid was 4,050 cc with an output of 3505 cc of urine. The maximum concentration of sulfamerazine in the blood was 68 mg of the free drug. The hydrogen ion concentration of the urine was maintained above a p_H of 8. At no time were sulfamerazine crystals observed microscopically in freshly voided specimens of urine. There was no evidence of gross or microscopic hematuria, and the patient had no symptoms referable to the urinary tract. She had several emeses, complained of a headache, and appeared mentally confused and depressed for a short time. The procedure failed to sterilize her blood.

On the basis of this and similar observations, we have recommended at the University Hospitals that in patients receiving sulfadiazine or sulfamerazine a fluid intake should be maintained so that the urinary output during a period of twenty-four hours ranges between 1000 and 2000 cc. At the same time, enough sodium bicarbonate should be administered so that the p_H of the urine is 7.5 or more. Obviously, such a procedure is carried out in patients whose clinical condition does not contraindicate these procedures. This applies particularly to patients having renal dysfunction or cardiac failure. It should be emphasized that renal complications due to sulfapyridine, sulfathiazole, sulfadiazine and probably sulfamerazine may be due to factors other than the precipitation of crystals. There is considerable evidence that renal failure may be associated with a direct toxic effect of the sulfonamides on the renal parenchyma and also due to hypersensitivity phenomena. It is doubtful that alkalinization would be of much benefit under such circumstances.

Sulfamerazine appears to be tolerated quite well by children and small infants. No toxic reactions were encountered in 15 infants under 1 year of age.

CONCLUSIONS

1 Sulfamerazine was administered to 116 patients having a variety of clinical conditions. Fifteen of these patients were infants under 1 year of age.

2 Sulfamerazine appeared to be as effective as sulfadiazine in the therapy of 40 cases of pneumococcal pneumonia or bronchitis. Sulfamerazine was less effective than sulfathiazole in the treatment of staphylococcal sepsis. Thirty-three patients with streptococcal infections responded as well to sulfamerazine as a comparable group did to sulfadiazine.

3 Two cases of meningitis due to type B influenza bacilli and 3 patients with meningococcal meningitis recovered following therapy with sulfamerazine.

4 Compared to sulfadiazine, when sulfamerazine was given orally adequate blood concentrations necessitated smaller doses given less frequently.

5 Sulfamerazine does not appear to be any more toxic than sulfadiazine. The drug did not produce any demonstrable neurologic complications. Sulfamerazine caused less nausea and vomiting than sulfapyridine, and fewer skin eruptions and instances of drug fever than sulfathiazole.

6 Two instances of nonfatal urinary tract complications were produced by sulfamerazine. The complication appeared to be due to the extrarenal precipitation of crystals resulting in the mechanical obstruction of a free flow of urine. There is evidence that an adequate fluid intake and alkalinization of the urine may prevent such complications.

THE SIMPLIFIED TREATMENT OF GONOCOCCIC OPHTHALMIA NEONATORUM WITH CHEMOTHERAPY

MARVIN L. BLUMBERG, M.D.

AND

MORRIS GLEICH, M.D.

Resident Pediatrician and Director of Pediatrics, respectively,
Harlem Hospital

NEW YORK

Cases of gonococcic ophthalmia neonatorum continue to appear in spite of the routine instillation of silver nitrate into infants' eyes at birth. The records of the New York City Department of Health¹ show that a total of 213 cases of gonococcic ophthalmia were reported from 1938 to 1942 (through October). Evidently, then, the disease is still a serious problem.

Previous to the use of the sulfonamides in the treatment of gonococcic ophthalmia of the newborn, the

disease was prolonged, treatment was exhausting and complications were frequent, often resulting in blindness. Therapy ranged from repeated copious lavages with various antiseptic solutions to cauterization of the conjunctivas with silver nitrate and even to canthotomy and midtarsal incision. Local measures were occasionally supplemented with intramuscular injections of nonspecific proteins.² Sulfanilamide was first used in the treatment of this disease in the form of a weak solution for local irrigation.³ Mullen⁴ used the drug orally as well as locally in solution, while Panneton⁵ insufflated powdered sulfanilamide or sulfapyridine into the conjunctival sac. In the past two years effective and rapid cures have been reported with the oral use of sulfon-

amides by Lewis,⁶ Wong,⁷ Sweet⁸ and others. All these investigators also used local instillations of mild protein silver, mercurochrome or other antiseptics, topical application of silver nitrate and frequent irrigations.

A comparative study of three groups of cases of gonococcic ophthalmia neonatorum at Harlem Hospital is presented in order to demonstrate the simplification and efficacy of the new therapy of the disease. In all cases the criteria for diagnosis were edema and inflammation of the lids, purulent discharge and the presence of gram negative intracellular diplococci in the smear of the discharge. The criteria for cure were the disappearance of these symptoms and the absence of gram negative diplococci from smears taken from the conjunctival sac.

In the first group (January 1934 to December 1937 inclusive) there were 30 cases, of which 16 were transferred to other hospitals with special eye services when the diagnosis of gonococcic ophthalmia was made. The remaining cases, treated at this hospital with local and general measures before the advent of chemotherapy, are summarized in table 3. In all the unaffected eye was protected with some such device as a Buller shield, while the infected eye was treated with repeated copious irrigations of boric acid solution and frequent instillations of 10 to 25 per cent mild protein silver. The duration of the illness ranged from six to forty-six days. In 5 cases (35.7 per cent) complications developed. In 1 baby arthritis of the left great toe and of both wrists appeared on the sixth, seventh and eighth days of therapy respectively. The joints were aspirated and gram negative diplococci were found in smears of the pus. Another infant developed a subcutaneous metastatic abscess which had gram negative intracellular diplococci in the aspirated pus. Two babies contracted gonococcic infection of the second eye on the second and fifth days of therapy respectively. The ankles of one became swollen but were not aspirated and so the condition was not proved to be gonococcic arthritis. In a fifth case, in which both eyes were involved at the onset, a corneal ulcer on one eye developed in spite of mild protein silver, boric acid irrigation and silver nitrate applied topically. Two patients were taken home on the fifth day before cure was effected, and 1 patient died of infectious diarrhea of the newborn on the sixteenth day of treatment with the ophthalmia still present.

In the second group (January 1940 to June 1942 inclusive) there were 31 cases, of which complete records were available for only the 14 presented in table 4. These babies were all given sulfonamides orally in divided doses four to six times a day to a total daily dose of 1 to 1½ grains per pound of body weight. Seven infants received sulfapyridine, 4 sulfathiazole, 1 sulfadiazine, 1 sulfanilamide and 1 sulfathiazole for a day followed by sulfapyridine for four days. All were treated with frequent irrigations of the affected eye, 13 with boric acid solution, 1 with isotonic solution of sodium chloride. The unaffected eye was protected with a shield. Ten patients received instillations of 10 to 20 per cent mild protein silver. Only 1 baby (7.1 per cent), treated with sulfanilamide, developed a

regardless of the infant's weight, the severity of the symptoms and whether one or both eyes were involved at the onset. As soon as a case was diagnosed, it was isolated in a separate nursery. Sulfathiazole was given by mouth in the form of an emulsion with acacia 3 grains (0.2 Gm) of the drug initially followed by 1 grain (0.06 Gm) every four hours until symptoms dis-

appeared and the unaffected eye was not protected mechanically. The babies all tolerated the drug well showing no loss of appetite or weight nor any abnormal findings in their urines. Since the duration of symptoms and positive smears was only one to four days the therapy was brief (in 2 cases treatment was continued for six and nine days respectively, through error). Therefore routine

blood counts and drug levels in the blood were not determined. All infants in this group were observed in the hospital for at least one week after being cured. No complications or relapses were noted during this time or in the follow-up clinic. These cases are presented in table 1.

The results of the methods of treatment of the three groups of patients are compared in table 2.

SUMMARY AND CONCLUSIONS

1 The sulfonamides used in the treatment of gonococcal ophthalmia neonatorum have greatly decreased the duration of the disease and have practically eliminated complications.

2 Patients are now treated routinely at this hospital only with sulfathiazole by mouth. Local therapy and mechanical protection of the unaffected eye are apparently unnecessary.

3 Sulfathiazole in doses of 1 gram per pound of body weight daily cured our patients and prevented complications.

THE TREATMENT OF MENINGOCOCCIC INFECTIONS WITH SULFADIAZINE AND SULFAMERAZINE

(SULFAMETHYLDIAZINE, MONOMETHYLSULFADIAZINE)

MARK H. LEPPER, M.D.

LEWIS K. SWEET, M.D.

AND

HARRY F. DOWLING, M.D.

WASHINGTON, D. C.

Many observers have attested the value of sulfadiazine in meningococcal infections.¹ A previous report from this hospital on the treatment of meningitis with sulfadiazine included 24 patients with meningococcal meningitis. Since then we have continued to treat all patients admitted to the Gallinger Municipal Hospital with sulfadiazine² or, since March 1943, alternately with sulfamerazine and sulfadiazine. During this time there has been an increasing incidence of meningococcal infections in the District of Columbia as well as in the country as a whole. Through May 31, 1943 we had treated 118 patients with meningococcal meningitis (including the 24 cases already reported) and 3 patients with meningococcemia.

The present report includes a summary of the results obtained with sulfadiazine and sulfamerazine together with an analysis of the factors which influenced recovery or death. We have also studied the severity of the disease as the epidemic progressed and have attempted to correlate this with the results of therapy.

Miss Ruth Mayer rendered technical assistance.

From the George Washington Medical Division (Drs. Lepper and Dowling) and the Pediatric Service (Dr. Sweet), Gallinger Municipal Hospital, and the Departments of Medicine and Pediatrics, George Washington University School of Medicine.

3 Sulfadiazine and sulfamerazine for this study were supplied by the Lederle Laboratories, Inc.

PROCEDURE

Routine procedures in the diagnosis and treatment of these patients have been carried out as follows. As soon as a patient believed to have meningitis was admitted to the ward, a lumbar puncture was performed. On the specimen of spinal fluid obtained several examinations were made. A cell count and a Pandy test were done. Smears of the centrifuged sediment were made. They were stained with both methylene blue and Gram's stains. If organisms believed to be meningococci were seen typing by means of the Neufeld technic was attempted. Cultures were planted in tryptose-phosphate or tryptose-phosphate-hemoglobin broth and on chocolate agar slants. A quantitative dextrose determination was made on the clear supernatant fluid by an application of Benedict's modification of the Folin-Wu method.⁴ After this study had established a presumptive diagnosis of meningococcal meningitis, a blood culture was obtained and treatment was begun. An initial oral dose of 6 Gm. of sulfadiazine or sulfamerazine was followed by 1 Gm. every four hours in adults. A proportionately smaller dose was given to children. For severely ill patients, especially those too stuporous to swallow, or for those who were vomiting excessively, the initial dose and a varying number of following doses were given as a 0.5 to 1 per cent solution of the sodium salt of the drug intravenously or subcutaneously. The sulfonamide drug was continued until the patient was afebrile for approximately seven days unless some indication for stopping the drug developed sooner. Frequent hemograms, urinalyses and blood urea nitrogen and blood sulfonamide determinations were obtained during the period of drug administration. Follow-up lumbar punctures were done on the second hospital day and again when discharge was contemplated. If the cell count had not fallen to 30 cells per cubic millimeter the puncture was repeated at weekly intervals until that level was reached. At this time the patient was allowed out of bed and was subsequently discharged. Additional lumbar punctures were done only when recovery was not progressing satisfactorily. Each spinal fluid specimen was examined in the same way as the one obtained by the initial lumbar puncture.

Patients who responded poorly to this regimen in the first twenty-four to forty-eight hours were considered candidates for serum therapy. After reevaluation of the clinical status of the patient and the laboratory findings, serum was given intravenously if it was believed indicated.

RESULTS

There have been a total of 118 cases of meningitis treated here using this routine. The etiologic agent in every case was established by one or more of the following methods: (1) positive spinal fluid culture, (2) a positive blood culture, (3) a smear containing demonstrable typical gram negative intracellular or extracellular organisms. All cases not fulfilling these criteria were omitted from this series. Whenever possible the organisms were typed.⁵ Seventy-three group I and 6 group II (alpha) organisms were found.

In addition there have been 3 cases of meningococcemia in which neither meningeal signs or symptoms nor any increase in cells in the spinal fluid occurred. Meningococci were cultured from the blood of all the e patients.

⁴ Benedict, S. R. The Determination of Blood Sugar. *J. Biol. Chem.* 64:207 (March) 1925.
⁵ Dr. Sara E. Branham of the National Institute of Health typed many organisms.

Among the 118 patients with meningitis 12 (10.1 per cent) died. Several clinical and laboratory features have been found to be related to prognosis. These factors include age, presence and duration of coma before treatment, number of organisms in spinal fluid and concentration of spinal fluid dextrose on admission and on the second day following therapy. We have measured the speed of recovery by the duration of coma, the duration of temperature elevation over 101 F by rectum and the duration of a spinal fluid cell count over 30 cells per cubic millimeter from the beginning of treatment. For these comparisons only the patients receiving sulfadiazine have been studied.

The distribution of patients by age is shown in table 1. Sixteen (13.6 per cent) of the patients were under 10 years of age, 66 (55.9 per cent) from 10 to 39 and 36 (30.5 per cent) were 40 years or over. No one under 10 years died, whereas 4 (6.1 per cent) of the patients in the intermediate age group (10-39 years) and 8 (22.2 per cent) of the patients over 39 years succumbed. The difference between the youngest group and the intermediate group is not

The number of organisms in the spinal fluid has been estimated from smears made in a uniform manner. "Many" organisms were reported when at least one organism was present in practically every field and several organisms were seen in most fields. "Few" organisms were said to be in a smear when approximately one half of the fields contained no organisms and relatively few organisms were present in any individual field. "Rare" organisms were said to be present when they could be demonstrated only after considerable search. When "many" organisms were present 9 patients among 42 (21.4 per cent) died, which is a significantly higher rate than for the patients with "few" organisms, among whom the rate was 5.2 per cent (3 deaths among 58 patients), and also higher than the group of 14 patients with "rare" or "no" organisms, among whom there were no deaths. The averages for the duration of coma, fever and elevated cell count again show a progressive increase the greater the number of organisms.

For the past year we have been doing immediate quantitative dextrose determinations in the spinal fluid

TABLE 1—Factors Influencing Prognosis of Patients with Meningococcic Meningitis Treated with Sulfadiazine and Sulfamerazine

Factor	Group	Number of Patients	Died		Speed of Recovery *		
			Number	Per Cent	Average Duration of Coma	Average Duration of Fever †	Average Duration of Pleocytosis
All cases		118	17	10.1	0.48	2.7	20.6

Includes only patients treated with sulfadiazine. † Temperatures permanently below 101 F by rectum.

statistically significant but the death rate in the oldest group is significantly greater than the rate in either of the other two groups as well as these two groups combined. It is also of note that the average duration of coma, fever and pleocytosis is progressively longer in each group and significantly so in the oldest group.

The presence of coma on admission shows a high correlation with the outcome. Among the 44 patients admitted in coma 12 (27.3 per cent) died, whereas not 1 of the 74 patients not in coma on admission died. This is highly significant when tested statistically. The average duration of fever for patients who recovered after being admitted in coma was 4.4 days and for those not in coma was 2.6 days. Moreover, the average duration of lymphocytosis was 26.1 and 18.1 days for patients with and without coma respectively. Both of these differences are of definite statistical significance. On the first day of coma 2 (8.3 per cent) died whereas of 20 patients admitted with coma of over 1 day's duration 10 (50 per cent) died. In addition, the average duration of illness before the onset of coma of the patients who died was 2 days, which is significantly greater than the average of 1.2 days for the patients who survived after being admitted in coma.

Forty of these patients had dextrose below 10 mg per hundred cubic centimeters and 6 (15 per cent) died. One (3 per cent) patient among 35 with dextrose between 10 and 49.9 mg per hundred cubic centimeters died and 1 (14.3 per cent) out of 7 with dextrose over 49.9 mg per hundred cubic centimeters died. Even though suggestive, these figures are not significant. The criteria of rapidity of recovery showed a slight but not significant trend in that the patients with higher dextrose levels responded more rapidly. Dextrose determinations were made on spinal fluids obtained on the second day. The results have been divided into three groups: first those which decreased or did not increase, second those which increased but not to 50 mg per hundred cubic centimeters and, third, those which returned to 50 mg per hundred cubic centimeters and above.

In the first group 1 out of 4 (25 per cent) died. In the second group 3 (9.7 per cent) among 31 died. In the third group 1 (2.9 per cent) of 34 died. None of these differences are statistically significant.

Other factors which were studied but showed no significant relationship to recovery were sex, race, duration of illness before treatment was begun, presence of

neurologic complications on admission, extent of rash, height of initial spinal fluid cell count, group of organisms and the presence of positive blood cultures on admission. Of these, the presence of neurologic complications on admission and the height of the initial spinal fluid cell count show a trend that might become significant when more cases are collected. These trends are that the presence of neurologic complications or of cell counts over 10,000 per cubic millimeter indicates a slower recovery.

Among the patients who recovered, the most frequent complications related to the infection were nerve palsies. These occurred in 21 patients. The majority of them were present on admission or when they could be identified as a comatose patient regained consciousness. They involved both sensory and motor nerves. The only sensory change noted was deafness, which was present in some degree in 8 patients. The motor nerves involved were the cranial third (oculomotor), fourth (trochlear), sixth (abducens), seventh (facial), eleventh (spinal accessory) and twelfth (hypoglossal), which were involved in 14 patients. In 1 boy there was a temporary spinal nerve palsy resulting in a transitory foot drop. More than one nerve was frequently involved, the greatest number in any 1 patient being six. The follow-up on the patients with nerve

The most significant complications of sulfadiazine therapy as well as the most common have been urinary in nature. The criteria which we recognize as diagnostic of urinary lithiasis are renal colic, gross hematuria and pronounced unexplained oliguria or anuria with or without azotemia or any combination of these. There have been 10 cases presenting one or more of these findings. In 6 of these cases symptoms developed at a time at which the drug could be discontinued safely. In all 6 cases an uneventful subsidence of symptoms occurred when this was done and fluids were forced. In cases in which further treatment of the infection was required the sulfonamide dosage was maintained, decreased or temporarily interrupted depending on the blood sulfadiazine level. Fluids were forced and attempts at alkalization were made with prompt and satisfactory recovery from renal symptoms. In only 1 case was cystoscopy needed. This was done on the third day of therapy and the drug was reinstituted in low dosage after a twenty-four hour interval.

Other toxicities from sulfadiazine have included 3 instances of rash with fever, 2 instances of fever alone and 1 instance of rash and conjunctivitis. One patient developed a transient leukopenia.

In addition to the foregoing patients, since March 1943 an attempt has been made to evaluate sulfameraz-

TABLE 2—Severity of Illness and Results of Treatment of Meningococcic Meningitis Treated with Sulfadiazine and Sulfamerazine

Treatment	Number of Patients	Severity of Illness						Results of Treatment

palsies has been too short for an evaluation of the eventual outcome. However, there has been no appreciable recovery to date in 6 of 8 patients who become deaf, whereas there has been some recovery in 12 of 15 patients with motor nerve involvement.

The other complications that we have encountered include 3 patients who had arthritis, 3 with tenosynovitis and 1 with conjunctivitis from which a meningococcus was cultured. All of these complications were of short duration.

TREATMENT

As seen in the third line of table 2, the mainstay of treatment in 96 cases was sulfadiazine. There were ten (10.4 per cent) deaths in this group. One half of these deaths occurred within the first twenty-four hours after admission. Eight of these patients received serum in addition to sulfadiazine. Twenty-two cases have been treated with sulfamerazine. There were two deaths (9.1 per cent) in this group, neither within twenty-four hours. In 3 of these cases serum was administered in addition to chemotherapy.

The response to therapy in the sulfadiazine cases in which survival occurred has varied from dramatic to satisfactory. The time taken for the patient to become rational and the temperature to become normal has been spread over a wide range, the extremes being 0.25 to 6.75 and 0.0 to 12.0 days and the averages 0.48 and 2.7 days respectively.

zine by giving alternate patients this drug and sulfadiazine. To date this study is unfinished but, as seen in table 2, 22 cases have been treated with each drug with two (9.1 per cent) deaths in each series. The age distribution was approximately the same in the two groups. The severity of cases as measured by presence of coma, dextrose content of the fluid on admission and the number of organisms in the initial smear showed that those patients who received sulfadiazine were slightly more ill. The somewhat more rapid response in patients who survived after receiving sulfamerazine may be correlated with their being less seriously ill. Only 1 person in the sulfadiazine group received serum. Three sulfamerazine treated patients have also received serum.

Three sulfamerazine treated patients had kidney complications as defined. One required cystoscopy. The others responded favorably to conservative treatment. Two instances of rash and fever, 2 examples of fever alone and 1 instance of leukopenia have occurred with sulfamerazine.

SERUM

As shown in table 2, 11 patients received serum. The only patient in the entire series who received serum intraspinally did so in another hospital immediately after the diagnosis. One other patient also received serum before admission. The course of these 2 patients was not different from the course of those who received no

serum One patient who was in diabetic acidosis was given serum as soon as the initial dose of sodium sulfadiazine was completed. However, the patient died within eight hours. Eight other patients received serum after having failed to respond to sulfonamide therapy in the first twenty-four to forty-eight hours. Four of these continued to fail and died. Four of these patients survived. In 2 it was felt that the recovery was definitely related to the administration of the serum in that a prompt improvement followed. In the other patients who recovered the actual value of the part played by the serum in influencing the outcome is questionable. Four of the 6 surviving patients developed mild serum sickness.

Of the 3 cases of meningococcemia without evidence of meningitis, 1 presented an acute onset of petechial rash and high fever and the other 2 showed a maculopapular rash, joint pains and fever. The first patient was treated with sulfadiazine with rapid subsidence of symptoms and no complication. The other 2 patients had recovered spontaneously by the time the diagnosis was established. They were observed for a prolonged period and were discharged in good condition.

Table 3 shows the effect of time of onset of the diseases as the epidemic progressed on the incidence, severity and recovery. From Jan 1, 1942 to June 30, 1942 there were 28 patients; from July 1, 1942 to Dec 31, 1942 there were 22 patients and from Jan 1, 1943 to May 31, 1943 there were 67 patients.

In the first time interval there were three (10.7 per cent) deaths, in the second interval three (13.6 per cent) deaths and in the third period six (8.5 per cent) deaths. It is seen, therefore, that no significant increase or decrease in mortality has occurred. On the other hand, the average duration of coma after treatment and of average time taken for temperature and cell count to return to the standards used have shown a prolongation in the more recent cases. The average duration of coma for the last two periods are both significantly greater than that for the initial interval, but the difference between these two compared with each other is not. The same statistical relationship holds for the average times for the temperature to return below 101 F and the cell count to return below 30 cells per cubic millimeter. There has also been an increase in the percentage of patients admitted in coma. In the first six months 8 (28.6 per cent) patients were admitted in coma. In the next six months there were 10 (43.4 per cent) patients and in the last five months 31 (46.4 per cent).

COMMENT

We have reviewed our experience with two drugs, sulfadiazine and sulfamerazine, in the treatment of meningococcic meningitis and analyzed the clinical and laboratory factors which bore a relationship to the outcome.

Our experience with both sulfonamides to the present time has been favorable. The over-all death rate of twelve (10.2 per cent) deaths among 118 patients compares satisfactorily with those in the literature for sulfonamide therapy.⁶

The incidence of neurologic complications has not been high. Only a few have not cleared up and the majority of these are nerve deafness. It is too early at this time to tell how many of these palsies will persist permanently. The incidence of toxicity, especially renal but also rash and fever with or without conjunctivitis is greater than generally reported for

sulfadiazine. Four and two tenths per cent of the sulfadiazine treated patients had fever, rash and conjunctivitis. Ten and four-tenths per cent of patients developed kidney complications. The large doses used as well as the dehydrated state of many of these patients on admission undoubtedly accounted for this high incidence of complications. Certain things must always be done to guard against this danger. The most essential is to secure an adequate fluid intake. At least 3,000 cc per day should be given. Excessively high doses of the drug should not be used unless necessary, and if the patient is showing satisfactory clinical progress in spite of a low blood sulfonamide level the dose should not be increased. Although we have attempted to keep the pH of the urine at or above 7.5 in only a few cases, our results have been similar to those obtained by others and have convinced us that this should be done whenever large doses of the sulfonamides are being given.

It is impossible for us to reach any conclusions about serum therapy as an adjunct to sulfonamides since we have treated too few cases. Occasional patients however, do show definite benefit from the administration of serum and we feel that it should be available at all times in case the response to sulfonamides is not satisfactory.

TABLE 3—Relationship of the Date of Onset to Severity of Illness and Prognosis

Several clinical factors have been found to be significant in prognosis following treatment with sulfadiazine.

Age is shown to be a most significant factor in mortality and in rate of recovery among surviving patients. Prior to the use of sulfonamides the prognosis of infants and elderly patients with meningococcic meningitis was extremely grave. Even with sulfonamide therapy results in these groups have been reported as still carrying higher death rates.⁷ Although we have had relatively few infants in this series, the response in the few we have had has been highly satisfactory and our group under 10 years of age is the most favorable one. These results are in keeping with those reported by Hodes.⁸ From our figures it would seem that by far the most unfavorable group to treat is that including patients of 40 years and over.

As stated no significant differences or definite trends could be brought out relating recovery to duration of illness before therapy. This is almost certainly caused by the pleomorphism of the disease and should not encourage delay in diagnosis and treatment. In any individual case we feel sure that time is an important item. We have data that relate duration in the indi-

⁶ Deaton, P. B. and Weserman, Ethel. Cerebro spinal Fever: Analysis of 355 Case Reports with Special Reference to Sulfonamide Therapy. *Brit. M. J.* 1: 497 (April 24) 1933.

⁸ Hodes, H. L. and Strong, P. S. Treatment of Meningococcal Meningitis with Sulfonamides. *J. A. M. A.* 119: 691 (June 27) 1942.

vidual case to outcome. Coma has been shown to be definitely detrimental, and any case which is delayed until coma is established certainly has been delayed too long. Furthermore we have shown that the duration of coma before treatment is started as well as the duration of the illness before coma occurred are both significant in the outcome of the case. We have had several patients treatment of whom has been delayed, who have slowly gone into coma and been in coma for as long as two days before treatment was begun. These cases, we feel sure would have been saved by earlier diagnosis and treatment. We feel, therefore, that early diagnosis and treatment are most essential.

Another laboratory manifestation which was found to be of significance in terms of mortality and duration of illness was the number of organisms in the spinal fluid. Apparently one can generalize and say that, the more organisms present, the more severe the illness is likely to be.

Prognostic value of spinal fluid dextrose has been emphasized recently by Rundlett, Gnassi and Price.⁹ They feel that a rising spinal fluid dextrose is of utmost significance. We have evidence that in general relatively high initial spinal fluid dextrose or rising spinal fluid dextrose is a good prognostic sign. However, in the individual case we have found it not completely reliable. In 4 of our patients who died there was a higher spinal fluid dextrose on the second day of illness than on admission. In 1 of these it was over 70 mg per hundred cubic centimeters. The duration of illness also did not follow spinal fluid dextrose levels more closely than the several other factors studied.

The time of onset in the epidemic was found to be important in speed of recovery but not in mortality. In considering this factor, all the morbidity measurements show a progressive increase in severity of the disease as the epidemic has progressed to the present time, and most of these trends are statistically significant. We feel safe in stating that there has been a definite increase in the severity of the illness in these cases although it has not been reflected in the mortality rate.

For some time it has been apparent that sulfonamides are effective in the treatment of meningococcic meningitis. However, it is well known that this disease is an extremely variable one in its severity, mortality rates varying from 20 to 90 per cent.¹⁰ It is very difficult, therefore, to evaluate a new therapy without accurately controlled experiments. On the other hand, increasing severity and mortality has been the rule in epidemic times until the peak is reached, and if an agent is effective throughout an epidemic its therapeutic value can be accepted. In our experience the mortality in meningitis treated with sulfadiazine has been both low and stable in a time of increased incidence when the virulence of the disease was increasing. We feel that this gives definite proof of the value of this drug in this disease.

We have begun to evaluate the efficacy of treatment with sulfamerazine as compared with sulfadiazine. Up to the present time the mortality rate is exactly the same in the two groups. The duration of illness and complications in relation to the virulence of the infection have been the same with the two drugs. Sulfamerazine seems to be as effective as sulfadiazine. In our hands it has been slightly more toxic, but the difference is not great.

SUMMARY

1 We have given sulfadiazine to 96 patients who had meningococcic meningitis, of whom 10 died, and sulfamerazine to 22 patients, of whom 2 died.

2 The presence of coma on admission and the age of the patient were the two most important factors in prognosis. One fourth of all patients admitted in coma died. If coma had been present longer than one day, one half of the patients died. No patients not in coma on admission died. Almost one fourth of patients over 40 years of age died.

3 The presence of numerous organisms or of a very low dextrose level in the initial spinal fluid are other unfavorable prognostic signs.

4 The incidence and severity of the disease treated by us has increased as expected in epidemic times, but the mortality rate has been kept constant.

5 Sulfadiazine is an effective agent in the treatment of meningococcic meningitis.

6 Sulfamerazine is apparently as good a therapeutic agent as sulfadiazine.

TREATMENT OF EPIDEMIC NEONATAL
DIARRHEA WITH SUCCINYL-
SULFATHIAZOLEALLAN H TWYMAN, MD
ANDGEORGE R HORTON, MD
INDIANAPOLIS

Outbreaks of epidemic diarrhea of newborn infants occurred in the fall of 1942 in Cleveland, Carlisle Pa., Detroit, Toledo, Ohio, Dayton, Ohio, and Indianapolis.¹ The disease is now appearing again in various parts of the Midwest. The disease is not new. It has occurred many times in the past in Europe as well as in this country.² Infants afflicted are usually less than 1 month of age. Those weighing over 7 pounds (3.2 Kg.) are victims as well as smaller and premature infants. The latter suffer the greatest death rate. The onset of the disease may be sudden or insidious. In the former case the baby begins to pass frequent, watery, greenish yellow stools, vomits and has fever. It may be drowsy or irritable. The weight loss may be alarming, and dehydration within a few hours may be severe. Fluid replacement, blood transfusions, changes of feeding formulas or the addition of pectin agar to the formulas have no satisfactory effect on the outcome of the disease. The mortality rate is usually near 50 per cent.³

A milder type of the disease has been described.² In this the stools are less frequent, the vomiting is not severe, loss of weight is slight or absent, and dehydration and fever may not be present. The recovery usually occurs in a week or ten days.

During the past several months we have observed diarrheal, neonatal deaths the cause for which we could not ascribe to parenteral infection, improper feeding or specific infection of the gastrointestinal tract, such as the colon-typhoid group of organisms. In our hospital the strictest of preventive medicine is being employed. Throat and stool cultures as well as complete physical examination of all nursery employees reveal no positive

factors. We have not found a causative agent for the disease. However we do report good results in a small series of cases using a treatment regimen hubbed about succinylsulfathiazole.

CLINICAL PICTURE OF EPIDEMIC DIARRHEA OF THE NEWBORN

The onset of the disease may be sudden or insidious, most of ours being sudden and unmistakably serious from the beginning. The infants rapidly lose weight and become worse as diarrhea and vomiting persist. Dehydration is severe and the infant appears very toxic. Stools number from four to five to fifteen or more in twenty-four hours. They are liquid and usually greenish yellow although other colors may be present. The temperature is usually near normal but may be elevated 2 or 3 degrees. Repeated stool cultures are negative for pathogenic organisms. In our series there was a single exception, in which case a culture of hemolytic streptococci was obtained. The fatal cases are usually terminated within ten days or two weeks often the cause of death being a complicating pneumonia.

The milder type of the disease, usually insidious in onset, has been observed by us. The clinical picture is one of barely discernible constitutional symptoms. The infant gradually begins to have more frequent stools soft in character and usually greenish yellow. Vomiting occurs infrequently. Dehydration and fever are not usually present. Weight remains stationary or there may be a slight loss. Usually after a week or ten days symptoms gradually abate and the infant progresses satisfactorily. There are gradations in severity of the disease and we have observed cases which could be classed with neither of the foregoing.

Succinylsulfathiazole, a comparatively new sulfonamide commercially known as "Sulfasuxidine,"⁴ has been used chiefly in the preparation of patients for surgery of the large bowel⁵ and for the treatment of bacillary dysentery.⁶ We have found no reference in the literature concerning its use in epidemics of neonatal diarrhea.

The original work on this drug by Firor, Poth, Knotts and others resulted from work designed to develop an agent that had powerful antibacterial activity in the bowel.⁷ Succinylsulfathiazole is ideal for this purpose. The workers mentioned have shown that the administration of the compound to animals alters the intestinal flora to such an extent that the number of *Escherichia coli* per gram of wet stool is reduced from a normal of ten million to one hundred. They also report that only 5 per cent of the ingested drug is eliminated by the kidneys and that little if any toxicity results from its administration. In fact, no toxic reactions of importance have occurred.⁸ The stools are softened and rendered odorless.

The action of the drug is purely local. Poth reports that succinylsulfathiazole is acted on by intestinal bac-

teria to cause hydrolysis and a yield of sulfathiazole locally in the bowel.

The suggested routine dosage consists in the oral administration of 0.25 Gm per kilogram as an initial dose this being followed by 0.25 Gm per kilogram in twenty-four hours. In the preparation of patients for surgery of the bowel, Gatch advises the administration of 0.5 Gm per kilogram as an initial dose followed by 0.5 Gm per kilogram daily, the dosage being divided into six equal daily doses for eight days.⁹

Because of its safety and proved value in reducing the number of coliform organisms, we have incorporated succinylsulfathiazole into the treatment of infectious neonatal diarrhea. We offer no explanation for the success of its employment, since no specific cause for the disease has been found.

OUTLINE OF TREATMENT

Treatment consists in (1) succinylsulfathiazole by mouth, (2) opiates by mouth, (3) vitamin K, (4) plasma or whole blood transfusions, (5) parenteral fluids and (6) protein milk formulas.

The newborn infants placed on our treatment routine cannot be classed as a selected group. In the early stages of the epidemic the infants were subject

Chart 1—Note sharp drop in number of stools in twenty four hours of infants treated with succinyl sulfathiazole.

to varying modes of therapy, which in most cases were supportive in character. The extreme fluid and electrolyte loss was combated with isotonic solution of sodium chloride, distilled water and dextrose, plasma or whole blood. Superficial veins were exposed for venoclysis and frequently as many as five or six of these procedures were required often with failure to reduce dehydration. Subcutaneous injections of fluids were only a moderate aid. Oral offerings were pushed to tolerance. Some physicians gave sodium sulfathiazole with no apparent relief of symptoms. Whole blood seemed to provide a short lived stimulus in a few cases and was interchanged with plasma and fluids.

Succinylsulfathiazole was first tried on 2 infants who were in advanced states of dehydration and were well below their birth weights. One of these was premature. The judicious administration of camphorated tincture of opium was concurrently instituted in an attempt to reduce diarrheal loss of the drug as well as of fluid. Since the number of stools was decreased soon after treatment was begun (chart 1) fewer injections of parenteral fluids were necessary. Diet was maintained on a protein milk formula for a relatively lengthy time. The response was gratifying.

⁴ Succinylsulfathiazole is registered under the proprietary name of Sulfasuxidine by Sharp and Dohme, Philadelphia.

⁹ Gatch W D. Personal communication to the author.

in both instances. Permission was obtained for further use of the drug. A routine of treatment was established and 9 infants subsequently affected were placed on a regular schedule. The most successful routine appeared to be one in which the opiate administration was adjusted to allow not more than three or four stools in twenty-four hours. Succinylsulfathiazole was given in somewhat larger amounts than generally recommended in the literature. Our standard was set at an initial dose of 2 grams per pound of body weight followed by one-sixth the initial dose every four hours. These are conveniently given with the regular feeding schedule and are apparently taken well by the infant. Gavage feeding was necessary in only 1 instance, although isolated instances of vomiting did occur.

It is important to administer vitamin K to infants treated with succinylsulfathiazole, since a reduction in the number of coliform organisms inhibits the absorption of the vitamin and hence promotes bleeding tendencies.

A large weight gain was not expected while the infants were on protein milk formulas. In fact, weight loss may continue for a short time following the institution of treatment and the increase may appear to be

Chart 2—Note the more rapid weight gain and shorter number of days of hospitalization of infants treated with succinylsulfathiazole

slow when the upturn begins. It is at this point that the diet should be bolstered by very gradual addition of carbohydrate to increase the caloric content of the formulas.

Withdrawal of the drug presented a problem, since there was no previous writing to indicate the proper length of time for its administration in this disease. Judgment in this respect was based on three factors: (1) number, color and consistency of the stools, (2) weight gain and (3) the general physical state of the infant. Because of the safety of the drug we attempted to err on the safe side and allowed one or two extra days before discontinuing its use. In 1 instance the drug was mistakenly discontinued for a two day period before the infant was adjudged to be in a satisfactory condition. The weight loss totaled 14 ounces and the stools became fluid and more numerous before the error was rectified. Treatment was then reinstituted as though in a new case and the baby responded satisfactorily.

Two cases were observed in which doses of succinylsulfathiazole were inadequate by our standards. Both infants died, these being the only deaths in our series of infants treated with succinylsulfathiazole.

Eleven control cases with which we compared our results were readily available, owing to the hesitancy

of many practitioners to institute treatment with succinylsulfathiazole. Selection of cases was determined only by permission of the attending physician. None were selected on a basis of severity of the disease.

SUMMARY

1 Epidemic neonatal diarrhea is confined chiefly to infants under 1 month of age. The onset may be sudden or insidious. The amount of dehydration, weight loss and toxicity depend on the severity of the disease. Stools are liquid and usually greenish yellow. Vomiting occurs in some cases. Fever is present in proportion to the extent of dehydration.

2 A brief review of the literature on succinylsulfathiazole reveals its proved value as a powerful agent in altering the intestinal flora. Its toxicity is minimal.

3 Of 22 cases of neonatal diarrhea, 11 were treated with succinylsulfathiazole. In the latter group there were only two fatalities, both of which we believe were due to inadequate dosage of the drug.

In the control series there were four deaths. The average number of days of hospitalization for those who recovered was almost twice that of the treated infants.

The weight gain for eight days of infants treated with succinylsulfathiazole was not matched in seventeen days by the untreated infants (chart 2).

There was a rapid reduction in the number of stools in twenty-four hours in those infants treated with succinylsulfathiazole in contrast to a very gradual reduction in the untreated ones (chart 1).

Determination of Ovulation—The presence or absence of ovulation is determined from the microscopic appearance of the endometrium in the premenstrual phase. The tissue is removed with the biopsy curet in the clinic at any time from the seventh day preceding the onset of menstruation to four hours after the establishment of the flow. Ovulation is now assumed to occur in normal ovulating adults on or about the thirteenth to the fifteenth day from the commencement of the cycle, and the changes seen in the normal endometrium from the assumed date of ovulation are quite striking. On the fifteenth day vacuolization of the cytoplasm occurs in the epithelial cells, most prominently in those lining the superficial glands, and the nuclei appear to migrate toward the surface of the cells, leaving a clear zone at the base. This effect is maximal on the seventeenth day, when the nuclei are normally lying in a row, each one toward the center of its own cell. The next nuclear move is toward the base, where they return about the nineteenth day. Secretion begins about the seventeenth day and by the twenty-first is well advanced. As the nuclei migrate toward the base, clearing of the superficial cytoplasm occurs, the cells swell and finally the superficial margins break down and active secretion occurs into the lumina of the glands. These glands dilate, the swollen cells give them a serrated or saw-toothed appearance in cross section, and they become tortuous. The stromal changes are just as distinct. On or about the eighteenth day small patches of edema appear in the more superficial areas, and the stromal nuclei, which hitherto had been closely packed and surrounded by very little cytoplasm, gradually become separated, until by the twenty-first day each is discrete from its fellow. The next change is an increase in the cytoplasm, this first occurs in the cells surrounding the small arterioles on the twenty-third day, and by the twenty-sixth day the edema is replaced by a sheet of stromal cells with large, pale nuclei and abundant cytoplasm. Just before menstruation commences the superficial layer becomes almost solid, and there is a striking resemblance of these stromal cells to decidual cells. The glands at this time are sometimes dilated, contain varying amounts of secretion and are lined by cuboidal epithelium.—Mackey, R. *Anovulatory Menstruation*, *M J Australia*, June 5, 1943.

CARDIAC DYSRHYTHMIA AND SYNCOPE

FROM THERAPEUTIC INHALATION OF CHLORINATED HYDROCARBONS

ARTHUR I. GEIGER, M.D.

NEW HAVEN, CONN.

The current wartime expansion in industry has unavoidably introduced some loss of supervision and control of health hazards by industrial health agencies and the exposure of workers to noxious agents is becoming a major public health problem. Prominent among the chemicals concerned in industrial toxicology are trichloroethylene and carbon tetrachloride which, because of their efficiency as lipid solvents, enjoy wide use particularly as degreasers of tools and machinery. Browning¹ listed twelve other major industrial uses for trichloroethylene and seven for carbon tetrachloride. Because of the high degree of volatility of these agents the inhalation of their fumes is a common mode of intoxication.

Although trichloroethylene is much less toxic than carbon tetrachloride,² Hamilton³ a decade ago reviewed the reports of 26 deaths among 284 cases of poisoning from trichloroethylene in German industry. A common factor in the fatalities discussed by both Hamilton³ and Browning¹ was antecedent loss of consciousness. Death was usually considered due to profound narcosis from excessive exposure, to phosgene poisoning from thermal decomposition products of trichloroethylene or to cerebral vascular damage similar to that more commonly observed in carbon monoxide poisoning.

In contrast to the many reported cases of industrial poisoning are the very few that have apparently followed even improper therapeutic use of trichloroethylene and the administration of this drug by inhalation is generally regarded as safe. Eichert⁴ reported 2 instances of toxic psychosis following excessive therapeutic inhalation and referred to only one other existing report. In all 3 instances Eichert commented on the difference in toxic manifestations exhibited by these subjects in contrast with the usual features of industrial intoxication. Several writers have expressed the opinion that the actual cause of industrial poisoning is partly or largely adventitious substances inhaled with the trichloroethylene.

I have recently encountered a remarkable case in which serious toxic manifestations of a character not hitherto described were observed in association with the infrequent therapeutic administration of small doses of medicinal trichloroethylene (and once of carbon tetrachloride) by inhalation. The case seemed noteworthy because of the unique character of the untoward effects induced and because of the new light that the experience may cast on a plausible cause of death not previously considered in acute fatal intoxication from chlorinated hydrocarbons.

REPORT OF CASE

Mrs. E. P. had always enjoyed unusually good health until her sixty-second year, when increasing, occasional discomfort in the right upper quadrant with mild dyspepsia and periodic vertex headaches with insomnia first appeared. Within eight months she lost 30 pounds (13.6 Kg.) and was admitted to the New Haven Hospital for study.

Examination revealed obvious loss of weight with a current weight of 127 pounds (57.6 Kg.). The admission blood pressure was 155/85. False teeth, palpable kidneys and cystocele and rectocele were the only other abnormalities on physical examination. Gallstones were disclosed by roentgenography. Other laboratory findings, including blood count, urine and stool examinations, Kalin test of the blood, gastric analysis and sigmoidoscopic and roentgenographic examination of the colon were all negative.

Cholecystectomy was performed following which appetite improved, and 14 pounds (6.4 Kg.) was gained in two months but some dyspepsia persisted and the vertex headaches increased gradually in severity and soon became daily occurrences. A peculiarity of the headaches was their prompt appearance on arising each morning and their subsidence during the night but simply lying down during the day had no favorable effect. Optical correction of a refractive error brought no relief. Reexaminations by consulting otorhinolaryngologist and neurologist did not disclose any apparent causes for the distressing headaches.

With the persistence of intractable headache for almost two years the patient became depressed, worried and discouraged. Because the usual variety of analgesic and sedative drugs had

Fig. 1—Control electrocardiogram preceding inhalation of drug.

afforded no relief for the headaches, the dispensary physician ultimately decided to try trichloroethylene by inhalation.⁵

The administration consisted usually of the contents of 1 ampule (1 cc.) of trichloroethylene dropped on a gauze square and placed in an ordinary drinking glass for inhalation by the patient in a reclining position. The procedure was sometimes repeated once within five or ten minutes.

On the occasion of the first inhalation the patient apparently fell asleep for several minutes, which was not unexpected for trichloroethylene is known as a general anesthetic. On awakening, the patient declared that the headache was completely gone. Three and again four days later she returned requesting more treatments, because headache had recurred, and again she obtained complete relief lasting a day or longer. On the latter occasions it was observed that the sleep induced so promptly by the inhalation was actually a profound loss of consciousness, for the patient could not be aroused and did not respond to painful stimuli. Moreover it was noted for the first time that the pulse became rapid and completely irregular during the inhalation but the blood pressure did not change significantly, color remained good and respiration seemed normal. On her regaining consciousness about one minute after the inhalation the heart action was again entirely regular.

The patient kept returning approximately weekly requesting further inhalational treatments and stating with evident gratification that the intervals of freedom from headache were gradually lengthening to about a week. During repeated inhalations of 1 cc. doses of trichloroethylene on six subsequent occasions the same loss of consciousness and transient arrhythmia of the

heart were noted each time and the headache was always promptly relieved.

Because of the patient's remarkable improvement not only in the matter of headache but also in her emotional behavior and general sense of well-being, the possibility was considered that suggestion might be a significant factor in the apparent

Fig 2—Continuous recording of lead 2. Each horizontal strip is of about 8.6 seconds duration. At A inhalation was begun, B (continued in figure 3), patient lost consciousness.

success of the treatment. To test this, a gauze square moistened with amyl acetate was substituted for the usual trichloroethylene without the patient's knowledge. No effects were observed on consciousness, heart action or headache. On another occasion a few cubic centimeters of carbon tetrachloride were administered again, partly as a control inhalation but also to see whether another chlorinated hydrocarbon would produce the same bizarre reactions that accompanied trichloroethylene. Inhalation of the carbon tetrachloride was again followed within a few seconds by cardiac arrhythmia and profound loss of consciousness precisely as had occurred previously with trichloroethylene. On this occasion a normal control electrocardiogram was obtained just prior to the inhalation (fig 1), and then lead 2 was recorded continuously throughout the experiment (figs 2 and 3). The tracing shows the prompt appearance of ventricular ectopic beats, which rapidly increased to multifocal beats of such profusion that they completely dominated the cardiac rhythm for almost a full minute after the administration of the drug had been terminated. Consciousness and normal rhythm reappeared practically simultaneously and, as usual, the headache was completely gone. The protocol for this experiment, which was typical of the previous experience with trichloroethylene, follows:

"Same old headache."

11 00 a m Control electrocardiogram three leads, then continuous lead 2. Blood pressure 160/90, reclining. Pulse 90.
11 01 Amyl acetate inhalation three minutes. No loss of consciousness, no pulse irregularity. Blood pressure 180/90. Pulse 120.

11 05 Carbon tetrachloride inhalation begun. Within thirty seconds slight irregularity of pulse noted.
11 06 Patient has just lost consciousness. Pulse now totally irregular. Blood pressure 184/110. Heart rate about 130. Color good, respirations normal.
11 07 Inhalation terminated. Color good.
11 08 Patient awakening. Heart still irregular.
11 10 Patient fully conscious. Blood pressure 180/110. Pulse 130, irregular.
11 15 "No more headache." Blood pressure 160/90. Pulse 90, regular.

Because the cardiac irregularity, as depicted by the electrocardiogram, seemed of ominous character, no subsequent administrations of chlorinated hydrocarbons to this patient were deemed permissible.

COMMENT

Loss of consciousness from inhalation of fumes of the chlorinated hydrocarbons is well known.⁶ It occurred in 117 of the 284 cases of trichloroethylene

Fig 3—Continuation of figure 2. C inhalation terminated, D patient regaining consciousness and recording was suspended for twenty five seconds. E, patient fully conscious.

intoxication reported by Stuber.⁷ Indeed, the drug has been given some trial as a general anesthetic⁸ and, because it is less volatile than ether, noninflamm-

nable and simple to administer it is being considered as the anesthetic of choice under field conditions in the tropics. Induction of trichloroethylene anesthesia usually takes from four to ten minutes and characteristically includes an obvious excitement stage, recovery is usually rapid and complete within five minutes after the inhalation has been discontinued. However the loss of consciousness repeatedly exhibited by our patient did not appear typical of the induction stage of anesthesia with this drug. The syncope was remarkable for the rapidity with which it developed, for ten to fifteen inhalations from a single crushed ampule usually led suddenly to unconsciousness without any excitement period whatever, and complete consciousness usually returned abruptly within one to two minutes after the inhalation had been discontinued. It seems unlikely that the concentration of the drug in the blood and central nervous system could have reached ordinary anesthetic levels so quickly and from such a small dose. That the patient's behavior was not merely an emotional reaction was apparent from her unresponsiveness to painful stimuli during the coma. There was no pallor, cyanosis or disturbance of respiration to suggest anoxia, nor was the relatively open method of administration by inhalation from a drinking glass likely to exclude a considerable admixture of atmospheric oxygen. Finally, the loss of consciousness was clearly not the result of greatly diminished cardiac output from disordered action of the heart, because the blood pressure never declined. One appears to be left with idiosyncrasy as an explanation although Hamilton⁹ stated that idiosyncrasy to the drug was unknown.

As to the mechanism by which the arrhythmia was induced, one can only speculate from the limited data, yet when our observations are viewed in the light of important earlier experiments a reasonably confident statement may be ventured. The current opinion is that the cardiovascular system in the intact animal or man is largely unaffected by both trichloroethylene and carbon tetrachloride,⁹ and cardiac arrhythmias have not been described. However, irregular action and fatal arrest of the heart from the inhalation of another chlorinated hydrocarbon, chloroform, have long been known. Levy and Lewis¹⁰ and Levy¹¹ have clearly demonstrated in cats that the immediate cause of death from chloroform is ventricular fibrillation which is invariably preceded by ectopic ventricular beats arising from multiple foci. They concluded from abundant experimental evidence that light chloroform anesthesia sensitizes the heart to factors (chiefly sensory stimulation and epinephrine) that may precipitate ventricular arrhythmias and fibrillation from the local action of the drug on the heart. Hill¹² supplied the next important link in the chain of evidence by showing that 50 per cent of patients develop multiple focus ventricular tachycardia for brief periods during the induction

stage or irregular conduct of surgical anesthesia under chloroform. The relation of these observations to the case herein reported is that the electrocardiographic picture of multiple focus ventricular ectopic tachycardia illustrated in figures 2 and 3 is indistinguishable from some of the records published by Hill and by Levy and Lewis as examples of ventricular prefibrillation produced by chloroform. The importance of the arrhythmia is obvious from Levy and Lewis's observation that final ventricular fibrillation is the next natural step in the expected train of events.

It seems undeniable that the irregular ventricular tachycardia which we observed represented an ominous prefibrillation arrhythmia, and as such it constitutes the first clear demonstration of a serious cardiac effect from the inhalation of trichloroethylene and of carbon tetrachloride. How common and real is this hazard? It appears rare and remote if judged by the fact that the irregular tachycardia has never been mentioned in connection with the inhalation of either drug. However, moderate acceleration of the heart rate is a common clinical observation, and one may wonder whether in the presence of tachycardia, a relatively slight irregularity may not escape clinical detection. Moreover while fatalities from acute trichloroethylene poisoning are commonly attributed to profound narcosis or ascribed to some other agent or cause yet sporadic instances of fatality or near fatality which might conceivably have been due to ventricular fibrillation induced by trichloroethylene or carbon tetrachloride are not difficult to find in the medical literature. The following may serve as examples.

Browning¹ writes as follows on page 177 of her monograph: "Two cases of death following exposure to trichloroethylene were also reported to the Home Office in 1934, but it was considered by the Senior Medical Inspector that death could not be ascribed to such exposure since in one the result of the post-mortem examination, including an analysis of the stomach contents, was thought to negative the possibility of acute poisoning by trichloroethylene or phosgene and revealed no obvious cause of death."

Veley¹³ referred to the case of a young woman who became unconscious and died while receiving a "dry" hair shampoo with carbon tetrachloride and cited another instance in which under similar circumstances the woman lost consciousness and developed a rapid and irregular pulse but recovered.

Chandler¹⁴ described an alarming experience with a 4 year old patient who lay prone while an adhesive tape dressing was being removed from the back with the aid of a sponge soaked in carbon tetrachloride. He wrote "The patient collapsed suddenly, respirations ceased, and the radial pulse became impalpable. Death appeared imminent. Artificial respiration was instituted. In about five minutes the pulse returned, as did active respiration, at first feebly, and then stronger. In about ten minutes the child was quite normal. The subsequent convalescence has been uneventful."

Could mild nasopharyngeal irritation by these vapors have initiated a trigeminocardiac reflex which perhaps together with unusual epinephrine release under slight

excitement, resulted in the production of numerous foci of ventricular hyperexcitability and discharge? Our experiment with amyl acetate, which might be viewed as a control, was negative in this regard, and, while the question probably remains unanswered, it would appear that trichloroethylene and carbon tetrachloride were specifically harmful by virtue of their chemical constitution rather than merely as mild irritants of the nasal mucosa.

If three of the chlorinated hydrocarbons can be incriminated as probable excitants of ventricular fibrillation, one should probably also regard the others of this group with suspicion. In fact, it is not difficult to find suggestive evidence of this effect in the literature on industrial toxicology. Thus, Collier¹⁵ included precordial pain and "attacks of rapid beating of the heart" among the symptoms he had observed in acute industrial intoxication from inhalation of dichloromethane used as a paint remover. Hamilton³ referred to a case of accidental death in which the victim had gone into a vat that had previously contained rubber dissolved in dichloromethane, the man was later found dead inside the vat. And Carozzi, quoted by Hamilton,³ remarked that workers in a dry cleaning establishment using mixtures of dichloroethane and trichloroethylene exhibited disturbances of cardiac activity along with other manifestations of intoxication.

In my opinion the inhalation of medicinal trichloroethylene, even in therapeutic doses, is no longer to be regarded as entirely without danger, and self-medication by patients should be permitted only under the direction of a physician who has first assured himself that such inhalation does not disturb the patient's heart action. Moreover, the use of trichloroethylene as a surgical anesthetic offers the threat of sudden death during light or irregular anesthesia by a mechanism precisely like that of chloroform. To the familiar hepatic and renal injury from carbon tetrachloride one must now add the possibility of its inducing ventricular fibrillation. Recognition of such hazards calls for even greater vigilance against industrial exposure to these vapors even in moderate concentrations and for brief periods. The indications in industry are for efficient ventilation or for the use of airline masks when ideal ventilation is not attainable.

SUMMARY

Profound loss of consciousness and multiple focus ventricular tachycardia, of an ominous type likely to lead to fatal ventricular fibrillation, developed repeatedly in a patient receiving therapeutic inhalations of medicinal trichloroethylene and also when carbon tetrachloride was experimentally substituted. The demonstrated type of cardiac irregularity probably explains some of the mysterious deaths reported in industrial exposures to vapors of the chlorinated hydrocarbons. Protection from such vapors should be afforded by efficient ventilation.¹⁶

16 After this manuscript had been prepared the author encountered a recent publication by R. M. Waters, O. S. Orth and N. A. Gillespie (*Anesthesiology* 4: 1 [Jan.] 1943) calling attention to cardiac arrhythmias noted by them in 10 patients and 7 dogs during anesthesia with trichloroethylene. Multiple focal ventricular extrasystoles and ventricular paroxysmal tachycardia were seen several times among 6 patients followed electrocardiographically. These observations confirm the contention that trichloroethylene shares with chloroform the danger of evoking ominous disturbances in the cardiac mechanism.

HEMANGIOMA OF VERTEBRA WITH COMPRESSION OF CORD

REPORT OF A CASE CURED WITH RADIATION
FOURTEEN YEARS AGO

MAJOR L. MINOR BLACKFORD
MEDICAL CORPS, ARMY OF THE UNITED STATES

Back pain is a common cause of admission to military hospitals in this country. A possible explanation of an occasional case is compression of the spinal cord by hemangioma of the vertebra. Hemangiomas of the vertebrae have been noted in more than 10 per cent of a large series of routine autopsies, more commonly in older persons and in females (Schmorl, quoted by most of the authors cited). While these hemangiomas rarely result in compression of the cord, when they occur in young males they seem to cause symptoms relatively often. Bailey,¹ in reviewing 26 reported cases with evidence of compression (1929), noted 4 in patients under 20 years of age (Globus and Doshay 13, Trommer 17, Guillaum 18, Gerhardt 18), and Kudryashev² more recently has reported one in a youth of 19.

In 1942 Ferber and Lampe³ assembled from the literature 52 cases of hemangioma of the vertebra with compression of the cord and contributed 1 of their own. To this number are added 12 more (Kudryashev,² Stern⁴ and 10 from the Mayo Clinic⁵), making a total of 65.

The symptoms resulting from compression of the cord by vertebral hemangioma are like those produced by any other type of extradural tumor, though they "probably resemble more the symptoms produced by a metastatic lesion of the spinal cord" in the opinion of Ghormley and Adson.⁵ According to these authors, Gold (1927) and Perman (1928) described the x-ray findings characteristic of the condition, although, as shown by Schmorl, a hemangioma may be present without being demonstrable roentgenographically. Bailey and Bucy⁶ said that in the pathognomonic roentgenogram may be seen "a reduction of bone density between parallel trabeculae which are increased in density." This appearance results from the independent growth of the angiomatous tissue which destroys certain trabeculae and causes the remaining ones to thicken.

Bailey and Bucy,⁶ in reporting the second case successfully treated by surgical measures (and subsequent irradiation), advocated laminectomy followed by irradiation. Kudryashev² operated on his patient but did not resort to roentgenotherapy until required to do so by a recurrence of symptoms six months later. Stern's⁴ patient, a woman of 73, died following operation. Surgical attack has carried a high mortality ("in virtually every report authors emphasize the difficulty and seriousness of the operation because of excessive bleeding"³), and a number of patients surviving operation have been submitted later to x-ray treatment. Ferber

and Lampe³ maintain therefore that the diagnosis can be established with sufficient surety to warrant roentgenotherapy as "the primary and sole method of treatment" provided improvement is discernible in a short time. This plan was followed in 12 cases reviewed by them and in their own case. Of these 13 recovery was complete in 10 and almost complete in 1 in the other 2 cases a few months after treatment there was "marked improvement" which may have become complete subsequently. In a fourteenth case (one of Freedman's three) complete paraplegia developed under roentgenography so laminectomy was performed in three stages eventually this patient also recovered.

Ghormley and Adson⁴ reported 5 cases treated with x-rays only. 1 did not improve. 2 showed great improvement and 2 were well four and six years respectively after irradiation. They advise laminectomy only when paraplegia has developed and often they follow operation with x-rays. They have operated on 5 patients with paraplegia. One died a few weeks after operation with complete paralysis below the level of the lesion. One, who became able to walk again, died six years later, apparently from a cerebral accident. One recovered clinically without the use of x-rays. Of the 2 who were also irradiated, one got much better and the other was well eight years after operation. Ghormley and Adson advise the use of a Taylor brace or corset in most cases.

REPORT OF CASE

On Christmas 1928 R. D. P., a college freshman who had "run the hundred in ten seconds" (the timing of this test was not official), encountered an empty cardboard box on the sidewalk. Kicking it enthusiastically, he was seized with a pain in the middle of the back radiating around the short ribs, especially on the right, and downward. When he overtook the box it seemed to him a good idea to repeat the maneuver "to get t' e kink out." He was unsuccessful in this attempt so he spent the rest of the day in bed. After that he suffered "a pretty constant sense of sharp pressure over the lower dorsal vertebrae which kept him in bed most of the time. Baking and massage with various liniments gave no relief. In February he felt a knot over the eleventh dorsal vertebra. Pressure on this caused excruciating pain which radiated around to the right groin. Movement of the back especially extreme flexion caused similar pain. Chronically diseased tonsils were hopelessly removed but there was no improvement.

On March 13 1929 the patient was a healthy looking youth of 18. A faint diastolic murmur was heard in the fourth interspace to the left of the sternum. The blood pressure fluctuated from 160/84 to 140/56. The back was held rigid. Over the right half of the eleventh thoracic vertebra a tumor about 4 cm in diameter protruded 2 or 3 cm. It looked and felt like a mass of tangled veins; neither pulsation nor bruit was observed. Below the eleventh rib to the right of the midline extending down to the ilium there was an area of hyperesthesia which went around and across the abdomen, though it was less noticeable in front. Sensory changes (diminution in touch pain and heat) were detected in the lower extremities. Position sense and vibratory sense however were unimpaired. The patellar reflexes were slightly hyperactive. Ankle clonus, present on the right was sustained for only a few jerks on the left. The bulbocavernosus reflex was absent on each side, and the anal sphincter reflex diminished.

X-ray studies of the spine were not enlightening.

When a needle was inserted into the tumor blood welled out to push back the plunger or the attached syringe. A few days later the Queckenstedt test established the presence of complete intrathecal block; the clear spinal fluid showed a heavy trace of globulin (Pandy and Ross-Jones tests).

To rule out possible spinal metastasis from a hypernephroma Dr. Montague L. Boyd was called in consultation. He found

no evidence of tumor of the genitourinary tract but attributed "an abnormal relaxation of the bladder and lack of sensitivity of the kidney pelvis to a lesion of the spinal cord."

While I suggested that the lesion might be a "vascular tumor originating in a congenital anomaly," it was the consensus that operation was indicated. We thought that, if complete removal of the mass should prove impossible, at least a biopsy might be helpful. Accordingly on March 20, 1929 the late Dr. Charles E. Dowman exposed the tumor. He encountered "tremendous hemorrhage (which) could only be controlled after packing with very hot gauze and eventually placing in a muscle transplant. Several pieces of tumor were curetted away for microscopic study." These bits were vascular and irritable; one contained a spicule of bone.

Dr. Everett L. Bishop rendered the following report:

"Microscopic Sections show two different structures. In some portions there is a moderately dense fibrous stroma in which are numerous small capillaries and numerous giant cells of foreign body type. These cells are somewhat smaller than those usually seen in bone tumors and the spindle cells of the stroma are somewhat hyperchromatic (fig. 1).

Fig. 1—Section showing fibrous stroma of slightly hyperchromatic spindle cells with interspersed capillaries of giant cells of foreign body type.

Other portions of the tumor show closely packed large and small vessels with poorly formed walls, the separating tissue being cellular and hyperchromatic spindle cells. No giant cells are seen in this area. A small area of newly formed osteoid material is seen (fig. 2).

Diagnosis. This is probably an osteogenic sarcoma of telangiectatic type, the diagnosis being based on the structure described in paragraph 2. In any type of malignant bone tumor areas of giant cells of epulis type may be found due to absorbing bone. In any event heavy x-ray is indicated.

In accordance with Dr. Bishop's advice Dr. W. Pope Baker on March 25 administered roentgenotherapy as follows: centered over the eleventh thoracic vertebra, port 20 cm in diameter, target-skin distance 45 cm, filter 0.25 mm copper and 1 mm of aluminum, 150 kilovolt peak, 15 milliamperes, ten minute exposure time. Within twenty-four hours the patient volunteered that he felt better. Roentgenotherapy was repeated using the same factors on the 27th and the 29th. The boy left the hospital a few days later free of symptoms. Dr. Baker gave him similar treatments on April 26, 28, and 30.

Frequent neurologic examinations were made. By June 14 ankle clonus had cleared up, the bulbocavernosus and anal reflexes were active and the boy was encouraged to lead a

normal life. By the end of the year there were no sensory changes, the precordial murmur was gone and the blood pressure determinations were consistently within the normal range. After he was graduated from college, examinations were made but once a year. Only bronzing of the skin with moderate telangiectasis (not present before roentgenotherapy) of the irradiated area remain.

In March 1942 the patient applied for a commission in the armed forces. The commission was awarded after I submitted a detailed report including the photomicrographs. When last heard from (April 24, 1943) he was on active service.

COMMENT

The article by Bailey and Bucy in *THE JOURNAL* of May 25, 1929 brought fresh hope to Dr. Boyd and me. The syndrome described in that paper so perfectly fitted this case that independently we jumped to the conclusion that it must be one of benign hemangioma. The roentgenograms were then restudied by me, however, and I was unable to detect the criteria set up

Fig. 2—Section showing predominantly vascular structure with hyperchromatic stroma cells and new osteoid tissue.

for the diagnosis of cavernous hemangioma. I regret that in the intervening years the original plates have disappeared.

On April 5, 1943 Dr. Bishop wrote:

On many occasions before leaving on service I have reviewed my sections of the tumor and each time I found it difficult to get away from the original diagnosis of osteogenic sarcoma. You will remember that I sent a section to [another specialist on neoplastic diseases], who also felt that the tumor was sarcomatous. However, on the basis of my frequent studies of his case and the subsequent developments, I am now inclined to the opinion that this was one of the peculiar hemangiomas of the vertebra rather than a fully malignant tumor. Certainly there is much in the histology of the biopsy fragments to indicate a vascular tumor—poorly formed blood spaces, hyperplastic endothelium—in addition to and in spite of the active and hyperchromatic spindle cell stromal cells. It would be fine to report a "cured" case of osteogenic sarcoma of the vertebra but you cannot do it on this case, the diagnosis would be questioned instantly and rightly so.

He added that he had seen the patient often when he was on duty at that station. "The last time I saw him he was in excellent shape (except for a touch of athlete's foot!)"

It is to be emphasized that the patient was kept under close observation for five months after the biopsy, and a complete neurologic examination was done at intervals of three months for an additional two years and at least once a year until 1942. During all these years he has led a normal, active life, and he has not needed a brace of any kind.

The high arterial pressure observed in 1929 is best explained in my opinion, as the result of worry over a serious illness (he knew that several of the attending physicians considered him doomed) by a boy with the temperament characteristic of a sprinter. The murmur, verified by Dr. R. Hugh Wood in 1929, has not been heard since that year.

Clinically, this is a case of hemangioma of the vertebra.

Since severe backache usually leads in time to x-ray studies of the spine, roentgenologists should bear in mind the possibility of hemangioma of the vertebra. Obviously, if compression of the cord has been great enough over a sufficient length of time, it will result in permanent damage and eventually in complete destruction of function. This, as brought out by Ferber and Lampe,³ explains the failure of roentgenotherapy in some cases. It must be stressed again that if irradiation alone is employed the patient should be watched carefully and, if improvement is not rapid, more drastic measures should be considered. Certainly surgery should not be attempted until roentgenotherapy has failed or until paraplegia has developed.

SUMMARY

Symptoms suggesting tumor of the spinal cord should lead to an investigation of the possibility of hemangioma of the vertebra. If such a diagnosis is made before the cord has been irreparably damaged, roentgenotherapy may be expected to effect a cure.

Sixty-five cases of hemangioma of the vertebrae resulting in compression of the cord have been assembled. In 12 of these a cure was reported from the use of roentgenotherapy alone. The patient who is the subject of this report was 18 years old when first examined three months after the onset of symptoms, roentgenotherapy by Dr. W. Pope Baker has given him fourteen years of health and he is now serving in the armed forces of his country.

Number of Doctors in China—Out of 12,000 doctors in China, probably over 6,000 are in private practice. An analytic study of these figures will reveal the following interesting points: (a) Only 60 per cent of the total are duly qualified doctors, the balance being apprentice trained practitioners who were permitted to register up to 1937, (b) 75 per cent are concentrated in the main ports of the six coastal provinces, (c) 92 per cent are under the age of 50, and 67 per cent under the age of 40, showing the relatively recent development of medical schools.

Probably one half of the population still believe more in native or herb medicine than in Western medicine. Thinking people, however, do not consider that this is a complicating factor of any permanent importance. As the health education of the masses is developed and as modern medical facilities are improved, the demand for native medicine will undoubtedly decrease. Unfortunately, the native herb doctors have introduced a political element into the problem, being numerically as strong as the Western style practitioners and politically influential in certain government circles. As a result some official recognition has been granted to the status of native medicine by the establishment of a college of native medicine under government auspices and by the local registration of native practitioners—Sze, Sze-ming. *China's Health Problem*, Washington, D. C., Chinese Medical Association, 1941.

Clinical Notes, Suggestions and New Instruments

ILLUMINATING MENINGOCOCCALMIA WITH PURPURA MENINGITIS AND FOCAL NECROSIS OF PITUITARY

WILLIAM H. GORDON, M.D. AND MICHAEL B. SHIMKIN, M.D.
BALTIMORE

This case of illuminating meningococcemia is reported because despite a clinical course typical of acute adrenal failure due to hemorrhage into the adrenals (Waterhouse-Friderichsen syndrome), necropsy revealed focal necrosis of the pituitary and no definite alterations in the adrenal glands.

HISTORY OF CASE

On December 2 a man aged 36 a physician was admitted to the hospital on Dec. 2, 1942 with the chief complaints of malaise and headache of about twenty hours duration.

During the evening of the preceding day the patient began to have malaise, headache and occasional slight chills. He came to work next morning and performed a necropsy. He did not feel well and vomited after eating lunch. His temperature was 38.5 C (101.3 F). On returning home he felt progressively worse and was sent to the hospital.

On examination the patient appeared acutely but not severely ill. The pulse rate was 96 and the respiratory rate 24 per minute. The pharynx was slightly reddened, the lungs were normal and there was no rigidity of the neck.

The routine urine examination revealed no abnormalities. The white blood count was 20,000 per cubic millimeter. A roentgenogram of the chest was normal.

On the morning following hospitalization (December 3) the temperature rose to 39.7 C (103.4 F) and the skin became covered with numerous petechiae. Large ecchymotic areas appeared rapidly on the legs, elbows, abdomen and back and there were petechial hemorrhages in the conjunctivas. There was no rigidity of the neck and Kernig's sign was negative. Blood for culture was taken. A platelet count showed 80,000 platelets per cubic millimeter, the clotting time was 5 minutes, 15 seconds and the bleeding time was 19 seconds. A spinal puncture showed the fluid to be under a pressure of 280 mm of water. The fluid was clear and contained 4 cells per cubic millimeter and 142 mg of sugar per hundred cubic centimeters.

A tentative diagnosis of meningococcemia was made and the patient was started on 3 Gm of sulfadiazine by mouth. Subsequently both the blood and the spinal fluid cultures were positive for *Neisseria intracellularis*.

At 2:30 p.m. on December 3 the patient was found in collapse, pulseless and with unobtainable blood pressure. There was further extension of the petechial and ecchymotic rash and he was cyanosed. A diagnosis of hemorrhage into the adrenal glands (Waterhouse-Friderichsen syndrome) was made. One thousand cc of isotonic solution of sodium chloride, 1 cc of epinephrine (1:10,000 solution), 0.5 Gm of aminophylline, 10 cc of adrenal cortex extract and 2 Gm of sulfadiazine were administered intravenously. The patient regained consciousness and vomited and the blood pressure rose to 80 systolic and 60 diastolic.

The subsequent course is recorded in the graph. The patient became comatose during the evening of December 3 and had a generalized convulsion. Next day signs of meningitis were present. The spinal fluid was milky and contained 11,100 cells, many of them polymorphonuclears. Intracellular gram-negative diplococci were seen on the smear. He was continued on sulfadiazine, a total of 13 Gm was given and on December 4 the blood level was 9 mg and on December 5 20 mg per hundred cubic centimeters. He also received 60,000 units of meningococcus antitoxin intravenously in two doses and two transfusions, one of plasma and the other of

whole blood. Adrenal cortex extract 10 cc every four hours for a total of 100 cc, two additional injections of 1 cc of epinephrine, four intramuscular injections of 5 mg each of dexamethasone acetate in oil and intravenous infusions of saline solution and dextrose were given for the adrenal insufficiency. Sedation by morphine and an oxygen tent were used supportively.

The blood pressure remained at a satisfactory level, but he did not regain consciousness and the pulse increased steadily in rate and became weaker in volume. He had several more generalized convulsions and was cyanosed.

On December 5 the blood pressure began to drop, the respiratory rate rose and coarse moist rales were heard throughout the lungs. The patient died rather suddenly at 4:15 p.m., about ninety hours after the onset of his illness.

Necropsy.—There were numerous ecchymotic areas on the skin, particularly on the lower extremities, some areas measured 3 by 4 cm in diameter. A petechial spot was present in each conjunctiva and there was extravasation of blood between the teeth and in the buccal mucosa.

The cerebral hemispheres and the cerebellum were covered with a layer of thin yellow-green exudate lying in the sub-

Course during last four days

arachnoid space and particularly prominent in the sulci and along the course of the blood vessels. Sections of the brain were normal.

The right lung weighed 560 Gm and the left 865 Gm. The left lung was consolidated in a spotty manner, and consolidation was also present at the base of the right lung. Mucopurulent exudate was expressed on cut section from the bronchioles. The heart weighed 280 Gm and the musculature was flabby.

The mucosa of the stomach showed multiple petechial hemorrhages which were also encountered occasionally in the small and large intestine.

The liver weighed 2,060 Gm and showed fatty infiltration. The gallbladder contained about fifty small gallstones. The spleen weighed 220 Gm and was firm and tense with slight softening of the pulp on section.

The adrenals were externally normal. On cut section petechiae were seen in the substance, particularly in the medulla of the left organ.

The kidneys weighed 200 Gm each. There were multiple petechial hemorrhages in the mucosa of the pelvis.

Microscopically sections of the brain showed irregularly distributed purulent exudate in the meninges. The cells were usually polymorphonuclears with some macrophages and red blood cells. Lymphocytes and macrophages also were observed.

in some areas of subcortical white matter. There were scattered small perivascular hemorrhages in the cerebral cortex. No organisms were found in the meningeal exudate.

In the glandular portion of the pituitary were three areas of coagulation necrosis, the largest measuring 2 by 5 mm, involving both epithelial and stromal elements. Suppuration and infiltration by polymorphonuclear cells were present in the adjacent meninges.

Sections of the lungs showed extensive patchy bronchopneumonia, congestion and focal hemorrhages. The exudate in the alveoli contained a moderate number of intracellular and extracellular, large gram-positive cocci. Focal necrosis of the mucosa and purulent exudate were encountered in the bronchi.

Sections of the adrenals showed irregular congestion with engorgement of the sinuses, in a few small areas hemorrhage was present. The cytoplasm of the cortical cells was irregularly vacuolized. Focal lymphocytic infiltration involved chiefly the medullary portion.

There were focal hemorrhages in the loose subepithelial connective tissue of the kidney pelvis, and superficially denuded areas in the small intestine. The heart showed a toxic myocarditis, the liver was infiltrated with fat, and there was slight cholecystitis.

The final diagnosis were (1) meningococcic septicemia, (2) meningococcic meningitis, (3) focal necrosis of the pituitary, (4) focal hemorrhages in the brain, meninges, lungs, adrenals and renal pelvis, (5) bronchopneumonia and bronchitis, (6) toxic myocarditis, (7) fatty infiltration of the liver and (8) cholecystitis with cholelithiasis.

COMMENT

The clinical appearance and the course of the patient were typical of hemorrhagic destruction of the adrenals in the presence of a fulminating septicemia, usually caused by the meningococcus. Ninety-six cases of this so-called Waterhouse-Friderichsen syndrome have been accumulated in the comprehensive reviews by Aegerter, Sacks, Kunstadter and Lindsay, Rice, Selinger and Robins.¹

The essential necropsy finding in these cases is massive hemorrhage in the adrenal glands, involving particularly the medullary portion. In this case the adrenals showed vascular congestion and a few microscopic areas of extravasation of red blood cells into the medulla. The morphologic alterations certainly were insufficient to account for the symptoms of acute adrenal failure and were merely a manifestation of generalized purpura that also involved the skin, the mucosa of the intestinal tract and the renal pelvis, the lungs and the brain. The focal areas of necrosis in the anterior pituitary were a striking finding. It is possible that the syndrome resulted from the damage to the pituitary, alone or in combination with the minimal adrenal changes and the effects of the septicemia.

Treatment with sulfadiazine, meningococcus antiserum, intravenous saline solution and dextrose, epinephrine and adrenal cortex extract were apparently temporarily effective. The patient recovered from the extreme collapse and the meningitis was improving. Similar measures were undertaken by Carey² in a woman aged 27 with meningococcemia who recovered after a clinical course that was compatible with the diagnosis of Waterhouse-Friderichsen syndrome. It seems improbable that this therapy protected the adrenals from massive destruction.

SUMMARY

A man aged 36 had fulminating meningococcemia with purpura, meningitis and focal necrosis of the pituitary. The clinical course was typical of the Waterhouse-Friderichsen syndrome, but no definite changes were present in the adrenals.

ETIOLOGY OF VARICOSE VEINS FROM AN ANATOMIC ASPECT, BASED ON A DISSECTION OF THIRTY EIGHT ADULT CADAVERS

SHERMAN A. EGER, M.D., AND STEPHEN L. CASPER, M.D.
PHILADELPHIA

A review of the recent literature relative to the etiology of varicose veins in the lower extremities shows that there is a tendency to accept certain factors as significant. These are chiefly heredity, trauma, increased postural strain, compression or constriction of veins and phlebitis, which may destroy the valves in the venous system (Christopher¹). With the exception of phlebitis, it was felt that the other factors per se do not play an essential role, as it seemed logical that there might be some basic anatomic factor to explain the development of this condition.

Valvular Distribution in External Iliac and Femoral Veins Proximal to the Orifice of the Internal Saphenous Vein in 38 Cadavers

	Number	Per Cent
No vein contained more than 1 valve		
Bilateral absence	3	7.9
Unilateral absence	11	28.9
Right	4	10.4
Left	7	18.5
Total absence on one or both sides	14	36.8
Valve absent in right external iliac but present in femoral	21	55.2
Valve absent in left external iliac but present in femoral	20	52.6
Valves absent bilaterally in external iliac but present in femoral	14	36.8
Valves absent bilaterally in femoral but present in external iliac	0	0
Valve absent in right femoral but present in external iliac	4	10.4
Valve absent in left femoral but present in external iliac	2	5.2

With this in mind, the following hypothesis is offered:

1. Since it is definitely known that there are no valves in the inferior vena cava and common iliac veins, it is the role of the valves in the external iliac veins to support the column of blood when in the upright position.

2. Absence of valves in the external iliac veins imposes a greater burden on the valves in the femoral veins.

3. Absence of valves in both the external iliac and femoral veins, above the orifice of the great saphenous, imposes an even greater burden of support on the valves of the latter vessel, in other words, on the superficial circulation resulting in varicosities.

In order to evaluate this theory, a study was made of 38 adult cadavers. This consisted in determining the respective number of valves in the external iliac and femoral veins to the level of the orifice of the great saphenous veins. The results of this investigation are clearly outlined in the accompanying table.

CONCLUSIONS

1. On an anatomic basis there is a 36.8 per cent minimal potential incidence of varicose veins in the lower extremities.

2. This potential incidence is further increased by the absence bilaterally in 36.8 per cent and unilaterally in 52.6 to 55.2 per cent of the valves in the external iliac veins with only one valve in each of the femoral veins above the orifice of the internal saphenous.

From the Jefferson Medical College and Hospital.
Dr. J. Parsons Schaeffer, director of the Daniel Baugh Institute of Anatomy, Jefferson Medical College, provided the material used in this study.
¹ Christopher, Frederick. *Textbook of Surgery*, ed. 3. Philadelphia: W. B. Saunders Company, 1942.

3 These varicosities should develop unilaterally in 28.9 per cent and bilaterally in 7.9 per cent

4 The left lower extremity should be involved approximately twice as frequently as the right

5 No vein in this series contained more than one valve

URINARY EXCRETION OF BISMUTH FOLLOWING LARGE BUT NONFATAL DOSE OF BISMUTH SUBSALICYLATE

JOSEPH SEIFTER, M.D., CLEVELAND AND
CAPTAIN FRANK M. McDONALD

MEDICAL CORPS ARMY OF THE UNITED STATES

A single dose of 9 cc of bismuth subsalicylate in oil containing 675 mg of elementary bismuth was injected into the left buttock of a man aged 47. The injection site was incised on the following day and two cigaret drains were installed. The lack of drainage and the x-ray film indicated that the bismuth suspension had spread along the fasciæ. The subject was released twenty-eight days after the injection. During this period of observation he developed pigmentation and ulceration of the oral and pharyngeal mucosæ, moderate fever, leukocytosis, albuminuria, and high levels of bismuth in the urine.

‡ Pooled specimens † Daily average for the pool

The bismuth in each of the twenty-four hour urine specimens was estimated by a method already described.¹ A total of 245.89 mg of bismuth was recovered in the sequence recorded in the table.

(The studies terminated when the patient's request for release was granted.)

The patient received a ninefold dose of bismuth subsalicylate and over a period of three and one-half weeks excreted 37 per cent of it in the urine. The maximum rate of excretion was gradually reached in two weeks, and half this value two weeks later. The percentage of bismuth excreted and the curve of excretion resembled those obtained with clinical doses of bismuth subsalicylate in oil² except that the daily levels were considerably higher.

From the Department of Pharmacology and the Department of Dermatology and Syphilology, Western Reserve University School of Medicine.

on these farms developed thiamine deficiency and died, although their rations when prepared contained a normally adequate amount of the vitamin. The antagonistic substance has not been identified, it may be an enzyme, for it is readily destroyed by cooking the fish. Green¹ and his associates believe that the observations on Chastek paralysis in animals may have some bearing on thiamine deficiency occurring in human beings in certain parts of the Orient. These investigators point out that beriberi is common in those places where raw fish, as well as thiamine poor polished rice, is consumed. However, not all types of fish are equally effective in destroying thiamine.¹ Jolliffe¹ found, on examination of four shipwrecked sailors who had subsisted for several weeks on raw fish and turtle, no clinical evidence of thiamine deficiency.

Still other examples of avitaminoses resulting from interference with an essential food factor are less well characterized. In all cases the diets of the animals were unusual, containing comparatively large amounts of uncooked egg white, raw fish oil, in some instances, drugs, and would not be normally considered as human food by persons in this country. These observations on animals are of considerable interest, nevertheless, for they help to elucidate an unusual type of mechanism involved in the development of some avitaminotic conditions.

Current Comment

CAN SELF-APPLIED JIU JITSU CAUSE DEATH?

Newspapers recently reported that a 14 year old school boy in Los Angeles was found dead under circumstances suggesting death from self-applied jiu jitsu, which the boy was in the habit of practicing zealously. Apparently, available medical literature does not contain any reports of death from self-applied jiu jitsu, but the Los Angeles case raises the question whether death can be so caused. Whether voluntary manual compression of the neck in jiu jitsu can cause fatal suffocation seems somewhat doubtful, because the respiratory center in the medulla is so much less sensitive to asphyxia than the motor cortical centers that the muscular contractions of the hands and arms probably would relax or fail of coordination before the cessation of respiratory movements. On the other hand, fatal cardiac syncope may result under various conditions, such as emotional crisis or pleural and other punctures and at times apparently even in the absence of structural, mechanical or toxicologic causes as ordinarily understood. When the cardiac reflexes are especially irritable, sudden death may occur from syncope through the carotid sinus reflex. The late Soma Weiss¹ in a consideration of rapid physiologic death under various conditions mentions a patient who after coronary thrombosis developed such sensitiveness of the carotid sinus reflex that turning the head or gentle

manipulation of the skin caused alarming transit asystole. From these considerations it seems possible that self-applied jiu jitsu may cause sudden death from syncope through the carotid sinus reflex. Certainly that possibility cannot be denied.

ANTIGENIC DIFFERENCES IN HUMAN SERUM

Unexpected reactions in transfusion with compatible blood as determined by cross matching or by blood grouping of the donor and recipient remain largely unexplained. Such reactions may increase in severity on successive transfusions. Are they due to corpuscular antigens not covered by the customary groupings, to the accidental presence of foreign substances of various kinds or to antigenic differences in the plasma or serum of the persons concerned? By absorption of precipitins in the serum of rabbits immunized with human serum Cumley and Irwin¹ obtained results which lead them to conclude that human serum does contain antigenic substances of such different specificities that it "may eventually be classified in terms of antigenic differences, much the same as has been done with the corpuscles." The genetics of any such constitutional serum antigens and their possible practical significance remain to be determined. In view of the increasing use of pooled human plasma the question arises whether serum and perhaps other antigens are present in plasma and then in that case what their fate is in pooled plasma. Here the effects of dilution as well as the possibilities of neutralization by antibodies (precipitins) will require consideration. In war services transfusion with pooled plasma so far is giving apparently uniformly favorable results. Comprehensive reports on the value and safety of pooled plasma will be of great importance in planning for the best means of transfusion after the war.

DIGITALOID DRUGS AND COAGULATION OF BLOOD

Some patients taking digitalis or related drugs appear to be excessively liable to coronary thrombosis and other symptoms indicative of increased coagulability of their blood. According to Macht,¹ who worked on cats and guinea pigs, heparinization of these animals prior to intravenous injections of ouabain and digitalis solutions significantly lowers the toxicity of these drugs—a mechanism which is probably correlated with the thromboplastic effect of digitaloid glucosides observed in vitro. Werch,² using rabbits, confirms part of Macht's observations. Digifolin given in large amounts intravenously to the rabbit causes a significant decrease in the coagulation time of its blood. These interesting observations have not yet been confirmed in the clinic nor are the therapeutic implications yet clear.

WAGNER-MURRAY BILL OPPOSED BY AMERICAN BAR ASSOCIATION

At the annual meeting of the American Bar Association held in Chicago August 23-26, both the assembly, which, in effect is the convocation of the membership at large and the house of delegates of the association opposed the enactment of Senate bill 1161 on the grounds that such an eventuality would 'establish federal control of the medical profession and the regimentation of doctors and hospitals. Further, the house of delegates put itself on record as being 'opposed to any legislation decree or mandate that subjects the practice of medicine to federal control and regulation beyond that presently imposed under the American system of free enterprise. The house of delegates then requested the association's board of governors immediately "to appoint a special committee to study, analyze and investigate S 1161 and to give publicity to the recommendations and findings of the special committee and the action of the board of governors thereon." The personnel of this special committee it is understood has already been determined by the board of governors and will be announced in the October issue of the *American Bar Association Journal*.

IMMUNIZATION AGAINST INFECTIOUS DISEASES IN LARGE CITIES

The exact extent to which preventive inoculations against diphtheria, smallpox, scarlet fever and typhoid are employed is unknown. Recently Collins and Council¹ reported a study of the frequency of immunizations against these diseases based on reports from over two hundred thousand households in twenty-eight cities of 100,000 population or more. The cities were selected as being representative for size and geographic location. Immunizations against scarlet fever and typhoid were negligible in frequency as compared with those against diphtheria and smallpox. Diphtheria immunizations were more frequent than smallpox vaccination during the preschool ages, but after the age of 5 the reverse was true. By the age of 8 61 per cent of the children had been immunized against diphtheria and 85 per cent had been vaccinated against smallpox. Although there was considerable regional variation, in no area were more than 5 per cent immunized to scarlet fever. A similar situation was found for typhoid, though the South was far above any other section in the percentage of immunizations to this disease. The West and North Central areas had the highest percentages of immunizations to scarlet fever. The West had the lowest percentage of diphtheria immunizations from birth through 7 years, but beyond that age the South was lowest. The Northeast intermediate states and South all had smallpox vaccination rates above 90 per cent by the age of 8 but the North Central and West were low, the latter having reached only about 60 per cent, the latter regions too have

the highest smallpox rates. It was concluded that in the preschool ages the percentages of children who had been immunized against diphtheria and smallpox increased definitely with the income. The same was true for diphtheria immunizations during the school ages, but there was little difference in smallpox immunization as between high and low incomes. Scarlet fever and typhoid immunizations increased with income in all age groups, thus indicating that these immunizations are largely the result of individual initiative rather than public programs. Conservative conclusions which might be drawn from this study are that smallpox and diphtheria immunizations have been more thoroughly "sold" to physicians and public health officials than have those against scarlet fever or typhoid, the number of cases of diphtheria and smallpox in the various regions reflect the degree of immunization of the population, the number of cases immunized to scarlet fever and typhoid, however, is insufficient in all communities to affect materially the disease attack rate.

CARRION'S DISEASE

Carrion's disease refers to both the severe anemic disease called Oroya fever and the less dangerous eruptive condition verruga peruana. The cause of both is infection with *Bartonella bacilliformis*. Calderon Howe¹ has recently investigated Carrion's disease in the valleys of the Santa Eulalia and Rimac rivers, where the disease is endemic, and in hospitals in Lima, Peru. The transmitter of the disease is the sandfly *Phlebotomus verrucarum* being the principal species involved. The disease gets its name from a Peruvian medical student, Daniel A. Carrion, who in 1885 inoculated some blood and tissue from a human verruga nodule into the skin of both his forearms. Some five weeks later he died of typical Oroya fever, this crucial experiment first proved that the eruptive disease and the generalized fever were of identical etiology. Complete protection from the disease can be assured by leaving before nightfall the narrow belt between about 800 and 3,000 meters above sea level where *Phlebotomus* occurs, since this wild sandfly feeds on human beings and animals only at night. Howe's reports are based on observations on 203 residents of the region in which bartonellosis is endemic. Blood cultures on special *Bartonella* medium were made for each person. An agglutination test, using formaldehyde treated suspensions of *B. bacilliformis*, was performed on serum from each patient. Most natives of the endemic areas contract the infection in some form in their earlier years. One attack of Oroya fever or of verruga peruana confers lasting immunity. Preliminary experiments on active immunization are inconclusive. Although the incidence of Carrion's disease is small and its geographic distribution restricted, its interesting features include the two distinct syndromes produced the strict geographic localization and the distinctive habits of the insect vector.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

DEDICATION OF WOODROW WILSON GENERAL HOSPITAL

The U S Army Woodrow Wilson General Hospital at Staunton Va was formally dedicated on September 1. Among the speakers on the program were Major Gen Norman T Kirk, Surgeon General of the Army, Major Gen Milton A Reckord, commanding general of the Third Service Command, and Hon Major A Willis Robertson, Member of Congress of the Seventh Virginia District. The 1,500 bed hospital, which was named in honor of Staunton's distinguished son Thomas Woodrow Wilson, the twenty-eighth President of the United States, is of brick construction and is located in the Shenandoah Valley, about 6 miles east of Staunton.

The professional staff at the time of the dedication was as follows:

ADMINISTRATIVE DIVISION

Col Sidney I Chappell, Commanding officer
Col Leonard D Hutton, Assistant post commander

PROFESSIONAL DIVISION

Col John Minor, chief of medical service
Lieut Col John H Lyons, chief of surgical service
Lieut Col Karl D MacMillan, chief of F E N T service
Lieut Col Harlan H Taylor, assistant chief of surgical service
Lieut Col Arthur J Williams, chief of X-ray service
Major James I Bunn, chief of outpatient service
Major Ben L Boynton, chief of physical therapy section of surgical service
Major Edgar F Cosgrove, chief of section of cardiovascular diseases of medical service
Major Welch M England, E E N T service
Major Raymond M Kay, assistant chief of medical service
Major Julius Newman, chief of plastic surgery
Major Edwin J Palmer, chief of neuropsychiatric service
Major Harold H Snyder, chief of urologic service
Major Terence L Tyson, chief of section of general medicine and chief of officers section of medical service
Major Erwin D Zeman, chief of laboratory service
Capt Howard M Ausherman, surgical service
Capt Leonard B Barnard, chief of orthopedic section, surgical service
Capt Margit C Carlisle, medical service
Capt Ephraim Horland, neuropsychiatric ward medical service
Capt Ewald M Jaffe, medical service
Capt John J Malee, surgical service
Capt Herman L Metzger, medical service
Capt William E Strecker, surgical service
Capt Richard L Sutton Jr, medical service
Capt Norman F Szold, surgical service
Capt William A Zavod, medical service
1st Lieut Frank R Boyer, medical service
1st Lieut William G Carman, medical service
1st Lieut James R Carroll, surgical service
1st Lieut Edwin C Faessler, surgical service
1st Lieut Harvey P Feigley Jr, surgical service
1st Lieut John S Hooley, surgical service
1st Lieut George A Hyder, surgical service
1st Lieut Brooke B Mallory, medical service
1st Lieut William G Motel, medical service
1st Lieut William S McCune, N Y J
1st Lieut Frederick C Reel, E E N T service
1st Lieut Arnold Royal, surgical service

MAJOR MOIR JR AWARDED DIS- TINGUISHED SERVICE CROSS

The War Department has announced that Major William Wilmerding Moir Jr, M C, U S Army, has been awarded the Distinguished Service Cross for extraordinary heroism in action in North Africa. Major, then Captain, Moir, together with members of his paratroop unit were shot down in their plane near Oran on November 8, according to an Associated Press report. The citation reads: "During the attack in the air and the ensuing strafing on the ground, Captain Moir distinguished himself by extraordinary heroism against the armed

enemy by inspiring administration of medical attention to wounded personnel before attention to himself, despite severe wounds to his head and back." Major Moir later was awarded the Order of the Purple Heart and is now in the United States serving at Fort Benning, Georgia. Major Moir graduated from the University of Minnesota Medical School in 1939.

CAPTAIN BUREM AWARDED PURPLE HEART

Capt Henry S Burem, M C, A U S, formerly practicing physician in Kingsport, Tenn, has been decorated with the Purple Heart, according to the Rogersville, Tenn, *Review*. Captain Burem, who was serving in North Africa with a motorized medical unit, noticed a land mine in the road over which his unit was advancing. He advanced in front of the unit and shot into the mine in order to explode it. He was hit in the shoulder by shrapnel and, according to recent reports, is recovering from the wound in Oran.

CONFERENCE OF MEDICAL CORPS OFFICERS

A three day conference of medical corps officers from all over the country was held recently at Jefferson Barracks, Missouri. The purpose of this conference was to make them familiar with their newly assigned duties as inspectors for the AAF Convalescent and Rehabilitation Training Program under the direction of Lieut Col Howard A Rusk, Office of the Air Surgeon, Washington, D C. This program is now functioning in the AAF regional hospitals at West Palm Beach and Coral Gables, Fla.

ARMY PERSONAL

1st Lieut Martin H Rush of Fair Haven, N J, who is on duty with the medical section at the Army Air Field at Rome, N Y, has been promoted to the rank of captain.

Brig Gen Eugen G Reinartz, commandant of the School of Aviation Medicine, Randolph Field, Texas, recently addressed the Medical Society of Milwaukee County in Milwaukee on "Aviation and the Doctor."

A testimonial dinner was given at the Statler Hotel in Washington, May 25, in honor of Major Gen James C Magee, whose term of office as Surgeon General of the Army expired on May 31. About two hundred and fifty officers of the medical department attended.

Lieut Col August H Groeschel, M C, has become assistant commandant of the Medical Administrative Corps Officer Candidate School at Camp Berkeley, Texas replacing Col George E Armstrong, who has received another assignment. Colonel Groeschel, formerly of Sussex, N J, previously was director of the department of training at the Medical Administrative Corps school since its founding in the spring of 1942.

Major Norman C Schroeder, formerly of Kenton, Ohio, was named post surgeon of the Army Air Force Technical Training Command School at Yale University to succeed Lieut Col Carl A Schuck. Major Schroeder graduated from the University of Michigan Medical School, Ann Arbor, in 1924.

NAVY

PERSONNEL OF A HOSPITAL IN THE SOUTH PACIFIC

(The following story was written by Sgt Garth P. James of Ironwood Mich a Marine Corps combat correspondent)

Somewhere in the South Pacific (delivered)—Members of a Navy hospital unit celebrated their first year of overseas service on the Fourth of July at this South Pacific base.

Pictured here is the medical staff. Seated in the front row are (left to right) Comdr John G. Manley, chief of surgery; Capt I. W. Jacobs, chief surgeon at the rear; Capt Robert P. Parsons, retiring commanding officer; Capt Franklin F. Murdoch, incoming commanding officer; Capt Richard C. Satterlee, executive officer; and Comdr Arthur C. Webb, dental officer.

Second row: Lieut Comdr William G. Mitchell, chief of medicine; Lieut Edwin I. Madden of the Dental Corps; Lieut (jg) Leslie L. O'Connor of the Chaplain Corps; Pharmacist Paul C. Law, U.S.N.; Lieut Angus M. Brooks (MC), U.S.N.; Lieut Comdr Sidney G. Kennedy Jr. (MC), U.S.N.; Lieut

Commander Webb was attached to the medical staff of Bellevue Hospital, New York, before entering the Navy in January 1942. His wife lives at 23 Mayflower Court, Freeport, N.Y.

Lieutenant Commander Mitchell lives at 214 Atlantic Street, Corpus Christi, Texas. He was associated with the Shriners West Texas Memorial Hospital, San Angelo, Texas, before entering the Navy.

Lieutenant Madden is a graduate of the University of Minnesota Medical School. His wife, Harriett M. Madden, lives at 705 Laurie Street, Alliance, Neb.

Lieutenant O'Connor is the chaplain of the unit. He attended the chaplains' school at William and Mary College, Williamsburg, Va., before coming here and is ordained a Presbyterian minister. His home is in Houston, Texas.

Pharmacist Law lives at 411 West 11th Street, Pueblo, Colo.

Lieut. Brooks, son of Mr. I. H. Brooks of St. Johnsbury, Vt., was associated with the Hartford Hospital, Hartford, Conn., before joining the Navy in April 1942. He is an anesthetist.

Members of a Navy hospital unit at a base in the South Pacific

Comdr James D. Hibbard, MC-V(S), U.S.N.R.; Lieut Comdr William A. Coates, MC-V(S), U.S.N.R.; Lieut Comdr Niel E. Eckelberry, MC-V(S), U.S.N.R.

Third row: Lieut (jg) Louis A. Williams, MC-V(S), U.S.N.R.; Lieut George E. Penn, MC-V(S), U.S.N.R.; Lieut Edward E. Hause, MC-V(S), U.S.N.R.; Lieut Robert C. Loigren, MC-V(S), U.S.N.R.; Lieut (jg) Julian P. Breillatt (MC), U.S.N.; Lieut Comdr Leon Bromberg, MC-V(S), U.S.N.R.; Lieut Comdr Bertrand I. Krehbiel, MC-V(S), U.S.N.R.; Lieut Comdr Alfred L. Duncombe, MC-V(S), U.S.N.R.; Lieut (jg) Bernard F. Duwel (MC), U.S.N., the personnel officer; Chief Pharmacist Comer L. Harvill, U.S.N.

Rear row: Lieut Comdr Harry B. Burr, MC-V(S), U.S.N.R.; and Lieut Comdr Paul H. Schraer, MC-V(S), U.S.N.R., the X-ray officer.

Commander Manley was the associate surgeon at St. Agnes Hospital, Philadelphia, before entering the Navy. He lives at 1444 South Bancroft Street in that city.

Captain Jacobs entered the Navy in April 1917. He is a specialist in X-rays and a graduate of Harvard Medical School. His home is in San Diego, Calif.

Captain Parsons also entered the Naval service in May 1917. A graduate of Harvard Medical School, he is a urologist. His home is at 53 West 83d Street, New York.

Captain Murdoch is a specialist in tropical medicine. He lives at 1801 Howard Avenue, San Carlos, Calif.

Captain Satterlee entered the Navy in 1917. He is a graduate of George Washington University Medical School, Washington, D.C., and lives at 1267 28th Avenue, San Francisco.

Lieutenant Commander Kennedy, formerly resident surgeon at the Grady Hospital, Atlanta, Ga., entered the Navy in February 1943. His wife, Elinor E. Kennedy, lives at 2100 East Mallory Street, Pensacola, Fla.

Lieutenant Commander Hibbard was associated with Wesley Hospital and Wichita Hospital, Wichita, Kan. His home is at 1208 North Imperial Street, Wichita, Kan.

Lieutenant Commander Coates is an X-ray specialist and was associated with the South Side Hospital, Bay Shore, N.Y., before he joined the Medical Corps. His home is at 143 East Main Street, Babylon, N.Y.

Lieutenant Commander Eckelberry was the assistant surgeon at Metropolitan Hospital and instructor in surgery at New York Medical College. His wife lives at Weston Road, Georgetown, Conn.

Lieutenant Williams entered the Navy in September 1942. A specialist in orthopedic surgery, he was the resident surgeon in that subject at the University of Iowa Hospital. His home is at 549 Logan Street, Southeast, Grand Rapids, Mich.

Lieutenant Penn was associated with the Flower Fifth Avenue Hospital, New York, as a specialist in diseases of the eye, ear, nose, and throat.

Lieutenant Hause entered the Navy in May 1942. Prior to that time, he was an assistant resident in neuropsychology at the University of California. His home is at 105 18th Avenue, San Francisco.

Lieutenant Loigren, son of Mrs. Ruth E. Loigren of Starkweather, N.D., joined the naval service in December 1941. He was associated with the University of Pennsylvania Hospital, Philadelphia, as a specialist in dermatology and ophthalmology.

Lieutenant Brillant lives at 1326 Nebraska Street, Vallejo, Calif

Lieutenant Commander Bromberg, son of Mr Sol Bromberg of Galveston, Texas, is a specialist in internal medicine. He interned at Robert Koch Hospital and the St Louis City Hospital, St Louis

Lieutenant Commander Krehbiel, a specialist in pediatrics, entered the Navy in April 1942. He interned at Isolation Hospital and City Hospital, St Louis. His wife, Ruth C Krehbiel, lives at 3024 Clark Court, Topeka, Kan

Lieutenant Commander Duncombe was associated with Moore Hospital Brockton, Mass and St Luke's Hospital, Middleboro, Mass. His wife Louise F Duncombe, lives at 38 Winthrop Street, Brockton

Lieutenant Duwel personnel officer here, lives at 128 Lexington Avenue, New York

Chief Pharmacist Harvill lives in San Francisco

Lieutenant Commander Burr, whose wife lives at 6407 Peerless Street Houston Texas joined the Navy in March 1942. He is a specialist in urology and was associated with Memorial Hospital St Joseph's Hospital and Jefferson Davis Hospital, St Louis

Lieutenant Commander Schrier is a specialist in radiology. He entered the Navy in February 1942 and was associated with the Pennsylvania Hospital, Philadelphia, and the Delaware County Hospital Drexel Hill, Pa

METHOD OF SELECTING PREMEDICAL AND PRE-DENTAL STUDENTS FOR ENTRANCE IN THE MEDICAL AND DENTAL SCHOOLS

The Bureau of Naval Personnel of the Navy Department has announced that students shall be selected for medical or dental training in the V-12 Program on the basis of their potential professional ability and on their records through the end of their third premedical term. Selection shall be made as early as practicable in the fourth term of the applicant's premedical work with the two following exceptions:

(a) For the first such selection, men who have already advanced beyond their fourth term will be considered on the basis of their work through the last term completed

(b) Former apprentice seamen V-1 and V-7 who were accepted by approved medical schools or accredited dental schools prior to July 1, 1943 will be assigned to the schools which accepted their applications without further review of their credentials by the Committee of Deans referred to

For both medical and dental students there is to be a committee in each naval district composed of deans of the medical or dental schools, or their representatives, in the district and the district training officer as a consultant member, which shall be requested to prepare lists of premedical and pre-dental students for consideration for medical training. The Bureau of Naval Personnel will assign students from these lists to fill available vacancies in approved and accredited dental and medical schools throughout the country on the following basis:

(a) In the case of a nationwide excess of qualified students, the same percentage of qualified students from the top of each list down is to be assigned to medical and dental training from each district

(b) All men selected in accordance with the foregoing procedure who complete premedical work at the end of a given Navy V-12 term are to enter medical or dental school before men finishing their premedical or pre-dental studies at the end of a later term

(c) Men selected for medical or dental training are to be assigned to schools in their districts if possible without violating (b). If not possible to assign men to schools in their districts, they will be assigned to schools in the nearest districts that have vacancies

(d) Men are to be assigned to the school of their choice if possible without violating (b) or (c)

SHIPS NAMED IN HONOR OF MEDICAL DEPARTMENT OFFICERS

The Bureau of Medicine and Surgery announced on August 23 that new naval vessels will be named in honor of the following medical officers:

J Douglas Blackwood Commander Blackwood (MC), USN, was killed in action on Aug 9, 1942 in the Solomon Islands

Rall Lieut Richard R Rall (MC), USN, was killed at Pearl Harbor on Dec 7, 1941

Miles Lieut (Jg) Samuel S Miles (MC), USNR, was killed in the battle of the Solomon Islands while serving with the First Marine Division

Bronstein Lieut (Jg) Ben Richard Bronstein (MC), USNR, died as a result of the torpedoing of the U S S *Jacob Jones* off Cape May, N J

Crowley Lieut Comdr Thomas E Crowley (DC), USN, was killed at Pearl Harbor, Dec 7, 1941

O'Reilly Lieut Edward J O'Reilly (DC), USN, was killed in action in the Solomon Islands in 1942

SIX NEW DISPENSARY HOSPITAL UNITS IN FLORIDA

Six new independent dispensary hospital units have been completed at six auxiliary airfields in Florida. According to the *Army and Navy Journal* each sickbay will contain ward facilities for 42 patients, including 4 beds for S O Q. The new units are under the control of Capt Bertram Groesbeck Jr (MC), U S Navy, whose headquarters are at the U S Naval Air Station, Pensacola. Each of these units will be provided with portable x-ray equipment, complete laboratory facilities, flight surgeons' instruments, dark room and examining room in addition to the usual medical, surgical and pharmacy facilities. Three medical and two dental officers will be assigned to each of these units which will serve as independent units in liaison with the main dispensary and the School of Aviation Medicine.

OFFICER PERSONNEL STUDY IN THE BUREAU OF MEDICINE AND SURGERY

According to the *Army and Navy Journal* of August 21 a study of utilization of officer personnel in the Bureau of Medicine and Surgery was completed by the Navy Management Engineer's Office on August 13. The personnel study was the second survey to be taken by the management engineer, a similar canvass of the Bureau of Aeronautics having been completed recently. Other bureaus will be covered also. The study was confined to one hundred and twenty-four officers of rank of lieutenant commander and below and was designed to search out and indicate appropriate action in cases of misplacement, to discover what billets can be filled by enlisted men or WAVES, and to discover instances in which officers are not fully and appropriately occupied by their duties.

LIEUT VICTOR S FALK JR RECEIVES SILVER STAR AWARD

Lieut Victor S Falk Jr (MC), U S Navy, received the Silver Star Award for caring for wounded on Guadalcanal under fire and for traveling aboard a disabled plane the next day while he cared for patients being evacuated. The famed "Bat Out of Hell" squadron of marine dive bombers, of which Lieutenant Falk is a member, fought through the battle of Midway and the Guadalcanal campaign and were the first to bomb the Munda Japanese base. They furnished support for ground troops mopping up on the island and have returned to action in the Solomons with Major Claude J Carlson of Seattle in command.

MISCELLANEOUS

THE DISTRIBUTING CENTER FOR
PARASITOLOGIC SPECIMENS

During 1943 the greatly increased expansion in the teaching of tropical medicine in medical schools throughout this continent brought to light a critical scarcity of adequate parasitologic material for instructional purposes. Accordingly a committee formed by the American Association of Medical Colleges and the National Research Council together with other interested agencies conceived a plan whereby such material might be gathered in the field and also exchanged to mutual advantage among teaching institutions. For this purpose a distributing center for parasitologic specimens was established and the Division of Parasitology and Tropical Medicine at the Army Medical School was designated to carry out this plan. The center at the Army Medical School is coordinated with the one recently established at the Army Medical Museum for the collection and distribution of tissue specimens from cases of tropical diseases.

Between Jan 1 and July 1, 1943 the distributing center supplied fifty-six army training centers and ninety-four hospitals, medical and graduate schools in the United States, Canada and Mexico with almost 24 000 specimens. This material consisted of 392 living cultures of protozoa, 1 573 vials of helminth ova and protozoan cysts, 17 775 malaria slides (chiefly supplied by the U S Public Health Service), 222 paraffin blocks of specimens of fixed tissues, 533 vials of entomologic specimens, 3 036 miscellaneous slides including whole mounts, smears from cultures and sections and 307 vials of adult helminths, scolices, segments and so on.

This material was received from fifty-five institutions including medical schools, zoology departments, army hospitals, the U S Public Health Service, various state public health services and other interested individuals. The list of generous contributing agencies follows:

UNIVERSITIES AND MEDICAL SCHOOLS

University of Alabama	Johns Hopkins University
University of Arkansas	University of Louisiana
Baylor University	University of Michigan
University of California	University of Minnesota
University of California at Los Angeles	University of Missouri
University of Chicago	New York University
Chicago Medical School	University of Pennsylvania
University of Colorado	Queen's University
Columbia University College of P & S	Rice Institute
University of Connecticut	University of Rochester
Cornell University	University of Southern California
Duke University	University of Tennessee
Harvard University	University of Toronto
Indiana University	Tulane University
Iowa State College	Washington University
	Yale University

ARMY CAMPS AND STATIONS

Army Medical Museum Washington D C	Greenville Army Flying School, Mississippi
Army Medical School Washington D C	Medical Dept 2653
Port Belvoir Virginia	Puerto Rican Dept Lab P R
	Fourth Service Command Laboratory

GENERAL HOSPITALS

Borden Oklahoma	Percy Jones Michigan
Letterman California	Walter Reed Washington D C
McClellan Texas	

HEALTH DEPARTMENTS

Florida State Board of Health

OTHER SOURCES

Bureau of Animal Industry U S D A	National Institute of Health Bethesda Md
Bureau of Ent & Plant Quarantine U S D A Washington D C	New York Public Health Service U S Public Health Service Columbia S C
Bureau of Ent & Plant Quarantine U S D A Florida	Rockefeller Foundation Brazil
Board of Health Lab Ancon C Z	Rockefeller Foundation Colombia
International Hospital Santo Domingo R D	Rockefeller Foundation Tallahassee Fla

Since the functioning of the center depends on a steady influx of such material every institution is urged to continue sending in all parasitologic specimens which can be spared and which

might prove valuable to another school. Both gross and microscopic specimens of parasitic worms and ova, arthropods of medical importance, protozoa, malaria and other blood parasites are particularly desired. Mailing containers, franked labels and shipping directions will be furnished on request. Shipments should be addressed to:

The Director
Army Medical School Att. Division of Parasitology
Army Medical Center and Tropical Medicine
Washington 12, D C

Cooperation in responding to this appeal will make possible the continuation of this valuable service.

BLOOD DONOR SERVICE

A Statement on the Functions of the American Red
Cross Blood Donor Service

Frequent requests are made to the American Red Cross to supply whole blood or blood plasma to individuals, to hospitals and to Army or Navy medical units in this country. The requests are based largely on misunderstandings of the functions of the Red Cross Blood Donor Service. In order to clear up these misunderstandings the following statement is issued with the approval of the Medical Services of the Army and Navy.

1 The Red Cross Blood Donor Service is the only agency through which the people of this country may give their blood to the Army and Navy for the production of dried plasma or serum albumin.

2 No facilities are provided for procuring whole blood from volunteer or paid donors for transfusions to be used either by the public or by Army and Navy medical personnel. The Red Cross Blood Donor Service is not a blood bank service.

3 All blood procured by the Red Cross Blood Donor Service is delivered immediately to processing laboratories, where it becomes the property of the Army or Navy. Most of the blood is processed into dried plasma or serum albumin to be used for the armed forces in foreign service or on naval vessels. Some of the blood however is processed into liquid plasma for use in military hospitals in this country. The Red Cross has no jurisdiction over the distribution of these blood substitutes and therefore cannot furnish them to any one.

4 The Medical Services of the Army and Navy have adequate supplies of liquid plasma for use in their hospitals in this country, which may be obtained by medical officers through regular channels as follows:

The source of supply for the Army has been set forth in an army circular letter which reads:

Thawed blood plasma (liquid plasma) is available to all army station and general hospitals within the continental United States. Liquid plasma will be supplied by processing centers as follows:

(a) Army Medical School Washington D C will supply the first second and third service commands.

(b) LaGarde General Hospital New Orleans will supply the fourth and fifth service commands.

(c) Fitzsimons General Hospital Denver will supply the sixth seventh and ninth service commands.

(d) The Eighth Service Command Laboratory Fort Sam Houston Texas will supply the eighth service command.

A supply of blood plasma for naval hospitals may be obtained by applying to the Commanding Officer U S Naval Medical School Naval Medical Center Bethesda Md.

5 All inquiries to the Red Cross from medical officers of the Army or Navy should be answered with the foregoing information.

6 All military units on foreign service or naval units on sea duty are being provided with adequate supplies of blood plasma or serum albumin as determined by the representatives of the Surgeon General's.

7 The Army and Navy have agreed to use blood plasma obtained only through regular military channels.

G CANN ROBINSON, M D
National Director
Blood Donor Service

Medical News

(PHYSICIANS WILL CONTRIBUTE A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

ARKANSAS

Dr Hearn Resigns as Director of Industrial Hygiene—Dr Roberts A Hearn, assigned by the U S Public Health Service as director of industrial hygiene, state board of health, has resigned to become medical director of the Indiana Division of the Republic Aviation Corporation, it is reported. His successor on the Arkansas board has not been named.

CALIFORNIA

Dr Ballard Joins Industrial Department at Los Angeles—Dr Francis E C Ballard, San Francisco, medical officer of the state bureau of industrial health, has been placed in charge of the industrial hygiene division of the Los Angeles City Department of Health.

Fund for Prevention and Cure of Disease—Science reports that the will of the late John H Eagle, Philadelphia silk manufacturer who died last month, bequeaths his estate, estimated at \$7,000,000 after a bequest of \$1,000,000 to Mrs Eagle, to the California Institute of Technology, Pasadena, and the Salvation Army. The fund for the institute will be used in the prevention and cure of disease and will be known as the John H Eagle Endowment. It provides for prizes for distinguished service to humanity in the fields of chemistry, physics, medicine and other scientific endeavor.

Changes in Health Officers—Dr Clifford V Mason assistant superintendent of the Fairmont Hospital of Alameda County, San Leandro, has been appointed health officer of San Leandro and Alameda County to succeed Dr Stanford F Farnsworth, who resigned to become health officer of Oakland. —Dr Stanley E Coffey was recently appointed health officer of the city of Orland, succeeding Dr Thomas H Brown, Dr Zerah P King was appointed health officer of the city of Sanger, succeeding Dr Benjamin H Viau, Carl W Clark succeeds Dr David C Cleave as health officer of Belvedere, Dr John L Vaught was appointed health officer of Dos Palos, succeeding Dr Paul A Lum.

INDIANA

New Professor of Ophthalmology—Dr Robert J Masters has been appointed professor and head of the department of ophthalmology at the Indiana University School of Medicine, Indianapolis. Dr William F Hughes, who has been chairman of the department since 1934, will continue teaching in the department. Dr Masters graduated from Indiana in 1918 and is secretary of the Section on Ophthalmology of the American Medical Association.

KANSAS

School Physicians Named—Dr Dale D Veimillion was elected president of the Goodland School Board, August 3. Dr Arthur C Gulick was recently elected a new member of the board. Dr James A Butin was elected vice president of the Chanute Board of Education, August 2.

Henry Asher Resigns from State Board—Dr Henry H Asher, Topeka, has resigned as director of the division of local health of the Kansas State Board of Health to become health officer of Alger and Schoolcraft counties, Mich. Prior to his appointment with the Kansas board, Dr Asher was health officer of Sedgwick County for two years.

Roster of Kansas Physicians—The Kansas State Board of Health recently released a new roster of physicians in the state as a substitute for the usual release printed by the state board of medical registration and examination and which was not published this year. The booklet of eighty-five pages contains the list of members of the Kansas State Board of Medical Registration and Examination, the list of members of the Kansas State Board of Health, a foreword by Dr Floyd C Beelman, Topeka, secretary of the board of health, a copy of G S 65-1004a (the Kansas licensure law), a list of states with which Kansas has reciprocity, a list of the health officers in Kansas by counties and towns, and a list of the physicians in Kansas both by counties and alphabetically, giving the license number of each physician.

MASSACHUSETTS

The Brigham Bulletin—In July the first issue of the *Brigham Bulletin* made its appearance under the editorship of Dr Robert S Myers, Boston. The bulletin is intended to be a medium between the Peter Bent Brigham Hospital, Boston, and members of its staff who are now in the armed forces.

The Warren Triennial Prize—Competitive essays for the Warren Triennial Prize will be received until November 15. The prize was set up in a fund by the late Dr J Mason Warren in honor of his father, Dr John C Warren. The accumulated interest is awarded every three years to the best dissertation considered worthy of a premium on some subject in physiology, surgery or pathologic anatomy, the arbitrators being the general executive committee of the Massachusetts General Hospital.

African Fever Studied at Harvard—Eight guinea pigs inoculated with a germ of African fever in the laboratories of the Firestone Tire and Rubber Company plantation in Liberia have been turned over to Dr David Weinman, instructor in comparative pathology and tropical medicine, Harvard Medical School, Boston, for study of the fever to find an effective antidote or preventive. It was stated that the immediate purpose of the study of the fever is to check its effect on troops in Africa and to plan postwar experiments of African diseases, newspapers reported.

Portraits Presented to Massachusetts Hospital—A portrait of the late Dr Reginald H Fitz executed by Margaret Fitzhugh Browne was unveiled by Mrs Reginald Fitz, daughter-in-law of the physician, during special ceremonies in the medical staff room of the Massachusetts General Hospital. Mrs Henry B Bigelow unveiled a portrait of her father, the late Dr Frederick Cheever Shattuck, the work of Mrs David Linn Edsall. Mrs Carol Lord Butler also unveiled a portrait of her father, the late Dr Frederick Taylor Lord, also the work of Margaret Fitzhugh Browne. Dr Nathaniel W Faxon, medical director of the hospital, accepted the portraits for the hospital. The three portraits were the gift of an alumnus of the medical service who wishes to remain anonymous.

MICHIGAN

Dr Whitehorn Lectures in Detroit—Dr John C Whitehorn, Henry Phipps professor of psychiatry, Johns Hopkins University School of Medicine and psychiatrist in chief, Johns Hopkins Hospital, Baltimore, will address the Michigan Society of Neurology and Psychiatry on September 23. His subject will be "Individual Issues in Postmilitary Psychotherapy."

Medical Conference—The department of postgraduate medicine at the University Hospital, Ann Arbor, announces a postgraduate medical conference, October 8. Subjects to be discussed include diabetic acidosis, diffuse vascular diseases, medical and surgical treatment of hypertension, management of chronic sinus disease, medical and surgical treatment of peptic ulcer, thymicolymphatic constitution, endometriosis and low back pain.

Two Bids Received for Mental Hygiene Clinic—News paper reports, August 12, indicated that Escanaba and Marquette submitted the only bids for the establishment of an upper peninsula mental hygiene clinic, allowed by an act of the legislature this year. The state will contribute about \$12,000 in professional salaries to the clinic, while the host county will be expected to provide about \$3,000 worth of quarters, equipment and secretarial services.

Collection of Blood for Civilian Use—The state department of health will sponsor a traveling clinic to begin about September 20 to collect blood plasma in Michigan cities to meet the needs of the state's civilian population, it was reported on August 24. The program will be financed out of \$20,000 appropriated by the legislature. Communities which donate blood to the program will establish their own plasma reserve from which physicians may obtain free plasma for their patients.

Course in Electrocardiographic Diagnosis—The department of postgraduate medicine of the University of Michigan Medical School, Ann Arbor, announces a postgraduate course in electrocardiographic diagnosis to be held November 8-11. Investigation consists of lectures, lantern slides and demonstrations as well as the examination under supervision of electrocardiograms from the files of the laboratory. There will be a fee of \$50. Additional information may be obtained from the department of postgraduate medicine, University Hospital, Ann Arbor.

MISSOURI

Kansas City Fall Conference—The twenty-first annual fall clinical conference of the Kansas City Southwest Clinical Society will be held at the Little Theater, Kansas City, October 4-6. Among the out-of-state speakers will be:

Dr. Harry L. Hyman, Philadelphia: The Present Status of Sulfonamide Therapy.
Dr. T. M. Dye, Pittsburgh: The Common Underestimated Vitamin Deficiency.
Dr. Frank H. Lyle, Boston: Peptic Ulcer from the Standpoint of the Surgeon.
Dr. Edward H. Rinehart, Rochester, Minn.: The Diagnosis and Treatment of Actual Endocrine Disturbance.
Dr. Cyril C. Sturges, Ann Arbor, Mich.: A Discussion of the Commoner Type of Anemia.
Dr. F. L. D. White, Boston: Newer Concepts Concerning the Course and Management of Coronary Heart Disease.
Dr. Charles Gordon Heyd, New York: Gallbladder Disease in Its Relationship to Intestinal Function.
Dr. William F. Menck, Iowa City: Prevention and Treatment of Toxicity in Pregnancy.

In addition there will be a round table discussion on 'Tomorrow's Results of Today's Research'. On Tuesday and Wednesday mornings a series of refresher courses will be held covering the various specialties. A military program has also been planned.

NEW YORK

Cancer Teaching Day—On October 7 a cancer teaching day will be observed at the Homer Folks Tuberculosis Hospital, Oneonta, under the auspices of the Medical Society of the County of Otsego, the Sixth District Branch of the state medical society, the Tumor Clinic Association of the State of New York, the division of cancer control of the state department of health and the state medical society. Speakers will include Drs. Norman Treves, Hempstead: On The Care of the Incurable Cancer Case; Gray H. Twombly, New York: Cancer of the Cervix; and Chevalier L. Jackson, Philadelphia: Cancer of the Larynx, Bronchi and Esophagus. At the evening session Drs. Andrew H. Dowdy, Rochester and George N. Scatchard, Buffalo, will discuss 'Cancer of Face and Lip' and 'X-Ray Aspects of Bronchogenic Carcinoma' respectively.

New York City

Hospital News—Direction of all medical teaching in the New York Eye and Ear Infirmary was taken over by the Columbia University College of Physicians and Surgeons on July 1.

Faculty Changes at Long Island College—Dr. Howard W. Potter, clinical professor of neurology and psychiatry and Nicholas B. Drever, M.A., associate professor of pharmacology, have been granted full professorships at Long Island College of Medicine, Brooklyn. Dr. Dorothy Loomis has been named assistant professor of pathology; this appointment is said to be the first in the history of the medical school in which a woman has been named an assistant professor. Dr. Loomis has held the Van Cott Fellowship in pathology at the school since 1936 and has been an instructor since 1938.

Facial Reconstruction Clinics Urged for Civilians—In discussing a new facial reconstruction program under army sponsorship, Nathaniel A. Olinger, DDS, in charge of the maxillofacial and surgical prosthesis department, School of Dental and Oral Surgery, Columbia University, advocated the immediate establishment of publicly supported clinics throughout the country to care for facial rehabilitation work. For the past six years Columbia University has been operating the only clinic of this kind, he said. New patients there are usually referred to psychiatrists who try to restore their confidence.

NORTH CAROLINA

Changes in Health Officers—Dr. Douglas H. Fryer, Leaksville, has resigned as the first full time health officer of Rockingham County to take over the city and county health activities in Bay City, Mich. He will be succeeded by Dr. Benjamin M. Drake, Carthage. Dr. Phares Y. Greene, Graham, has resigned as health officer of Alamance County, effective August 1, to devote his full time to private practice.

Second Treatment Center for Venereal Disease Planned—Arrangements are under way for the opening of a rapid treatment center in Durham, the second of its kind in the state (THE JOURNAL, August 7, p. 1024). Admissions are now being made at the first clinic in Charlotte, which will receive white and colored women only. Men will be admitted at Durham and those patients with treatment-resistant gonorrhea. At Charlotte preference will be given patients who are prostitutes, transients or uncooperative or who for other reasons cannot be satisfactorily treated in local clinics. All admissions will be channeled through county health officers. Patients will be admitted from all sections of the state at no cost to them.

OKLAHOMA

Wards for Poliomyelitis—Two wards of the University of Oklahoma School of Medicine Crippled Children's Hospital, Oklahoma City, have been set aside for the use of poliomyelitis patients. Dr. Charles M. Bickstein, formerly resident in pediatrics, University Hospitals, medical adviser of the Oklahoma Commission for Crippled Children, is working with Dr. Carroll M. Pounders and Dr. Don H. O'Donoghue, who are in direct charge of the poliomyelitis patients in the hospital.

Personal—Donald B. McMullen, Sc.D., associate professor and head of the department of hygiene and public health and associate professor of bacteriology, University of Oklahoma School of Medicine, Oklahoma City, was selected by the committee on the teaching of tropical medicine of the Association of American Medical Colleges to go to Central America during the month of September to observe methods of tropical disease control. Dr. McMullen was to spend about three weeks at a United Fruit Company Hospital and at least a week with the local field unit of the Office of the Coordinator of Inter-American Affairs. Dr. James D. Osborn, Frederick, has been appointed a member of the National Board of Medical Examiners for a term of six years.

PENNSYLVANIA

Dr. J. Moore Campbell Named Deputy State Secretary of Health—Dr. John Moore Campbell, Jr., former director of health conservation, has been appointed deputy state secretary of health in charge of medical affairs. Dr. Campbell has been a member of the state health department for many years. In 1911 he became pathologist in the state department's Philadelphia laboratory and three years later moved to Harrisburg to be in charge of communicable disease control work.

District Meeting—The Second Council District of the Medical Society of the State of Pennsylvania held its annual meeting at the Berkshire Hotel, Reading, September 8. A feature of the meeting was the presentation of fifty-year testimonial certificates to Drs. Harvey F. Scholl, Prospect Park, George C. Webster, Chester, Charles H. Schoff, Media, and George F. Seiberling, Allentown. The speakers on the program included:

Dr. George P. Muller, Philadelphia: Surgical Treatment of Bronchiectasis.
Dr. Robert L. Underhill, Pittsburgh: Our State Medical Society During Wartime.
Dr. Augustus S. Keeb, Altoona: Is Medicine Drifting Toward a Socialistic System?
Dr. Walter F. Donald, on Pittsburgh: Balancing Available Medical Service Between Armed Forces and Civilian Population.
Dr. Chauncey L. Palmer, Pittsburgh: Recent and Pending Health Legislation.

The county medical societies of Berks, Bucks, Chester, Delaware, Lehigh and Montgomery are included in the second district.

Philadelphia

Hospital Award for Staff Members—Dr. Rudolph Winston recently received the first annual award as the outstanding member of the staff of Mercy Hospital. The award, consisting of a scroll, was established by the hospital staff to honor a member who in their estimation had been the most outstanding during the previous year. Dr. Winston was selected for the first award on the basis of the fact that for the past two years he sacrificed his lucrative practice to give full time in study at the Graduate School of the University of Pennsylvania. According to Dr. Henry M. Minton, director of the hospital, it was felt that the sacrifice which he made in order to improve his medical knowledge felt to be of great benefit to Mercy Hospital was worthy of commendation and public approval.

Changes at Woman's Medical College—New appointments to the faculty of Woman's Medical College of Pennsylvania include those of Dr. Calvin M. Smyth, Jr., as clinical professor of surgery; Dr. Rubin M. Lewis, clinical assistant professor of surgery; and Dr. Miriam Bell Mount, Lebanon, Pa., clinical assistant professor of medicine. Promotions at the school include:

Reberta Hafke, bring Ph.D., professor of physiology.
Dr. Eunice L. Stockwell, professor of ophthalmology.
Dr. William T. Lemonson, clinical professor of surgery.
Dr. Frances Sulwell, Ph.D., associate professor of anatomy.
Dr. Charles F. Buile, clinical assistant professor of surgery.
Dr. Margaret DeRonde, clinical assistant professor of pediatrics.
Dr. Margaret K. Hard, clinical assistant professor of dermatology.
Dr. Dorcas M. Kullian, clinical assistant professor of therapeutics.
Dr. Marion West, clinical assistant professor of medicine.

TEXAS

Rockefeller Foundation Sponsors Lectures on Psychosomatic Medicine—Dr. Jacob S. Kasanin, assistant clinical professor of psychiatry, University of California Medical School, San Francisco, recently lectured on psychosomatic medicine at the various U. S. Army hospitals of the Eighth Service Command, under the auspices of the Rockefeller Foundation.

Personal—Dr. Edward H. Cary, Dallas, was recently chosen president of Group Hospital Service, Inc., of Texas to succeed the late J. H. Grosedose, D.D. Dr. Cary was formerly treasurer—The Woman's Auxiliary to the Smith County Medical Society gave a dinner in honor of Dr. Albert Woldert on July 21, observing his fiftieth anniversary in the practice of medicine in Tyler—Dr. Laurie Mackelchney, Fort Worth, was appointed July 20 as superintendent of the Wichita Falls State Hospital, succeeding Dr. Barton W. Dorbandt.

Clinical Staff Named for Cancer Hospital—According to the *Texas State Journal of Medicine* the board of regents of the University of Texas recently announced the appointment of the following Houston physicians, all of whom will serve without salary, as members of the clinical staff of the M. D. Anderson Hospital for Cancer Research: Drs. Judson L. Taylor, surgeon, John H. Foster, otolaryngologist, Everett L. Goar, ophthalmologist, Herbert T. Hayes, proctologist, Joseph B. Foster, orthopedic surgeon, Robert A. Johnston, obstetrician, Benjamin Weems Turner, urologist, James Greenwood, neurosurgeon, Culver M. Griswold, dermatologist, Moise D. Levy, physician, David Greer, pediatrician, Ernst W. Bertner, gynecologist, and Fred C. Elliott, D.D.S., stomatologist. Experimental work has been under way at the old Baker Home, 2310 Baldwin Avenue, Houston. New clinic buildings are now under construction on the site (*THE JOURNAL*, August 21, p. 1197).

GENERAL

Board of Pediatrics—The American Board of Pediatrics will hold its written examination locally under a monitor, Feb. 4, 1944. The oral examination will be held in Philadelphia on March 25-26 and in San Francisco on May 6-7.

Fire Prevention Week—The week starting October 3 has been designated by President Roosevelt as "Fire Prevention Week." In a statement to the press the President is reported to have said that the war program is menaced by an alarming increase in preventable fire losses. "These preventable fires," he said, "are being measured in thousands of workers killed and disabled, vast destruction of critical raw materials, food and other vital supplies for our armed forces and civilian population, the ruin of war plants, factories, homes and machinery—in many cases for the duration of the war."

Mrs. Milligan Named to Head Women's Field Army—Mrs. Lucy R. Milligan, New York, formerly director of the women's division of the National Association of Manufacturers, has been appointed national commander of the Women's Field Army of the American Society for the Control of Cancer, 350 Madison Avenue, New York. Mrs. Milligan, who has been a member of the national advisory board of the Women's Field Army since its organization in 1935, is president of the National Council of Women. Dr. Florence Rena Sabin, Denver, who was recently elected a director of the American Society for the Control of Cancer, was chosen an honorary national commander of the Women's Field Army.

Accidental Deaths Increase—A total of 3,991 accidental deaths for twenty-one reporting states was reported during the first six months of 1943. The National Safety Council states that this indicates only a 3 per cent increase despite increased employment and high speed production. Of the fourteen states showing increases the four recording increases of more than 50 per cent were Alabama, Arizona, Texas and Missouri. Increases ranged from 3 per cent in New York and Oregon to 78 per cent in Arizona. The largest decrease in accidental deaths for the half year period were reported by Illinois and North Carolina, both of which had checked accidental deaths 22 per cent over last year's record.

New Sustaining Members of Nutrition Foundation—Abbotts Davies of Philadelphia and the American Lecithin Company of New York have become sustaining members of the Nutrition Foundation, New York, and Mr. C. R. Lindback and Mr. Adrian D. Joyce, president and chairman respectively of the two groups, have become members of the board of trustees. In a release, August 31, the Nutrition Foundation stated that it is now receiving \$237,000 annually from thirty-seven food and related manufacturers to support basic research in the science of nutrition. The foundation is supporting seventy

basic studies in thirty-eight institutions in the United States and Canada. Grants-in-aid amounting to \$302,840 have been paid to these institutions since the organization of the foundation, March 12, 1942.

Regional Meetings of Chest Physicians—The Pennsylvania chapter of the American College of Chest Physicians will hold its annual meeting at the Bellevue-Stratford Hotel in connection with the meeting of the Pennsylvania State Medical Society in Philadelphia, October 6. The New York State chapter will hold its fall meeting at the Hotel Biltmore, New York, October 15, with the following speakers among others:

Dr. Chevalier I. Jackson, Philadelphia, A Simple Bronchopulmonary Nomenclature and Its Clinical Application
Dr. Richard H. Overholt, Brookline, Mass., Experiences with Pulmonary Resections in Pulmonary Tuberculosis
Brig. Gen. Shelley P. Marietta, assistant surgeon general, U. S. Army, Washington, D. C., Rehabilitation of Military Personnel as Carried Out in the Army
Dr. George G. Ornstein, New York, Idiopathic Spontaneous Pneumothorax, Incidence and Pathogenesis

Dr. J. Winthrop Peabody, Washington, D. C., president of the college, will be the guest speaker at a luncheon meeting. The Indiana chapter will hold its meeting in connection with the annual session of the Indiana State Medical Association at the Claypool Hotel, September 28. Herman E. Hilleboe, senior surgeon, U. S. Public Health Service, will speak on "Tuberculosis Control in Industry."

Resolution Urges Abolishment of Communion Cup—Announcement has just been received of a resolution adopted by the National Tuberculosis Association at its annual meeting in May recommending that the governing heads of church organizations that use the common communion cup adopt some method of "administering the sacrament that is in conformity with our knowledge of good hygiene and public health practice." The resolution was adopted unanimously and submitted to Bishop Tucker of the Episcopal Church for presentation at its annual convention in October. The resolution follows:

WHEREAS, It is a well established fact that one case of tuberculosis comes from another that the infectious agent, the tubercle bacillus, is contained in the sputum of those who have the disease and that this bacillus may be conveyed from mouth to mouth through the use of a common drinking cup,

WHEREAS, This menace to health has been recognized in most if not all, of the states by legislation prohibiting the use of the common drinking cup but notwithstanding certain church organizations continue to use the common communion cup in their services, therefore be it

Resolved That the Board of Directors of the National Tuberculosis Association at the annual business meeting held in St. Louis May 6, 1943 respectfully calls the attention of the governing heads of the church organizations that use the common communion cup to the danger of transmitting communicable diseases in this way and recommends that they adopt some method of administering the sacrament that is in conformity with our knowledge of good hygiene and public health practice.

B Complex Award—Nominations are solicited for the 1944 award of \$1,000 established by Mead Johnson and Company to promote researches dealing with the B complex vitamins. The recipient of this award will be chosen by a committee of judges of the American Institute of Nutrition. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who, in the opinion of the judges, has published during the previous calendar year January 1 to December 31 the most meritorious scientific report dealing with the field of the B complex vitamins. While the award will be given primarily for publication of specific papers, the judges are given considerable latitude in the exercise of their function. If in their judgment circumstances and justice so dictate, it may be recommended that the prize be divided between two or more persons. It may also be recommended that the award be made to a worker for valuable contributions over an extended period but not necessarily representative of a given year. Membership in the American Institute of Nutrition is not a requisite of eligibility for the award. To be considered by the committee of judges, nominations for this award for work published in 1943 must be received by the secretary, Arthur H. Smith, Ph.D., Wayne University College of Medicine, Detroit, by Jan. 10, 1944. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate the task of the committee of judges in its consideration of the nomination.

CANADA

Honored for Study of Medical Care—Science reports that Dr. Alfred Hardisty Sellers, medical statistician, department of health, Toronto, squadron leader, Royal Canadian Air Force, has been awarded the Professional Institute Medal of the Professional Institute of the Civil Service of Canada in recognition of the important contribution made by him in the study of hospital statistics in Ontario in connection with the cost of medical care.

LATIN AMERICA

Inter-American Congress of Radiology—The first Inter-American Congress of Radiology will be held in Buenos Aires October 17-22 under the auspices of the Argentine Society of Radiology (Sociedad Argentina de Radiología). A tentative program includes the following speakers:

Drs. Sabina Di Rienzo Cordova, Argentina and Dr. Luis Opazo, Chile
Ray Diagnosis of Spinal Infections

Drs. Carlos Butler, Montevideo, Uruguay, Leonardo Curman, Chile and Dr. Nelson Carvallo, Brazil: Cancer of the Breasts: Treatment and Results

Drs. Pedro A. Múnera, Argentina and Carlos Gomez, Colombia: Acute and Chronic Diseases of the Gastrointestinal Tract: Inflammation of the Jejunum, Dr. Múnera and Inflammation of the Colon, Dr. Gomez; Dr. Oscar Sofo, Peru: The Teaching of Radiology in America

Dr. Quirino Codras Thompson, Paraguay, will present an exhibition of roentgenograms on stenosis of the duodenum and Dr. Cassio M. Vilhena, Brazil, a similar exhibition on stomach ulcer. Dr. José F. Merlo Gomez is president of the Argentine Society of Radiology.

Health Activities in Latin America—A mobile dispensary for workers of the Pan American Highway has been provided. The first unit was placed in operation during June under the direction of Dr. Carlos Portillo and has been serving chiefly the area around Cholotea. Eventually three mobile units will be necessary for the entire highway in Honduras. The highway enters Honduras near the town of Goiscoran and passes from there through Nacaome, Jicaro Galán, Cholotea and San Marcos de Colon, leaving Honduras to enter Nicaragua shortly after passing through this last town. The work of construction is being carried on by North Americans and Hondurans under the direction of various construction agencies.

Society News—Dr. Ruy Rolim was recently elected president of the Brazilian Society of Ophthalmology. Other officers are Drs. Paiva Gonçalves and Jonas Arruda, vice presidents, Lincoln Caire, secretary, and José Alves Ferreira, treasurer. At the annual meeting of the Medical Association of San Juan, P. R., recently Drs. José A. Seim and Guillermo Ruiz-Cestero were elected president and secretary, respectively, for the ensuing year.

Hospital News—The eleven story Hospital Militar Central was recently opened in Buenos Aires. It has a large capacity and modern equipment in the different departments of all branches of modern medicine.

Scholarships—*Reader's Digest* has awarded three scholarships for study on the Kennel method in poliomyelitis in the University of Minnesota to Miss H. Rodriguez Brizuela, Miss J. E. Stella and Dr. Julio R. Calcamari. The scholarships were awarded through the Department of Public Health of Argentina and the Instituto Cultural Argentino.

Personal—Dr. Bernardo A. Houssay, head of the Instituto de Fisiología of Buenos Aires, has been made a member of the Royal Medical Society of London. Dr. José de Filippi has been awarded the 1942 prize of the Academia Argentina de Cirugía for his article on "Surgery on Heart Infarct", the prize is given annually. Dr. Rogelio E. Carratal of Buenos Aires was recently appointed honorary member of the Academia Latino-Americana de Neurología, Psiquiatría y Medicina Legal of Brazil.

Disease Control—The discovery of 460 cases of yaws in Guapi, Colombia, launched the idea for a campaign against the disease. A drive on malaria is also under way.

Social Security and Public Welfare Program Proposed—At the first National Congress on Public Welfare in Mexico City recently Dr. Gustavo Baz, secretary of public welfare, stressed the importance of raising medical standards in the republic by the careful selection of students and adequate facilities for study and research. He also recommended greater specialization among graduates of medical schools and announced that the department of public welfare was studying plans for a medical center in Mexico City with facilities for specialized research and practice in certain diseases. Dr. Baz stated that the objectives of the program would include the modernization of existing hospitals and construction of new hospitals throughout Mexico making medical care available to small communities now lacking such services; the control of malnutrition and the award of scholarships and fellowships to medical students and doctors. In the field of child and medical care Dr. Rodríguez Cabo proposed a unified child welfare code to coordinate existing child welfare laws; organization of a Central Technical Council to draw up a child welfare plan on a national

scale; complete maternity care, wider instruction in dietetics and providing needy children with free milk and meals. She also recommended a national drive to make the country more conscious of child welfare problems and needs. Dr. Juan Comas urged the congress to adopt measures necessary to meet the specialized needs of Mexico's Indians. Resolutions approved by the congress include coordination of public welfare services federally administered through an amendment to the federal constitution if possible, creation of facilities for substantiating need for welfare services and keeping pertinent records, planning of antepartum care to reduce infant mortality rate, creation of a central medical committee, as part of the department of public welfare, and establishment of suburban and rural medical centers to instruct mothers and prospective mothers in child care and antepartum care, an active campaign against tuberculosis, creation of visiting nursing and obstetric services, and pediatric and child welfare instruction to midwives and nurses attached to the department of public welfare.

FOREIGN

Clinics for New Zealand—The New Zealand government plans to establish health clinics in regions where groups of physicians are willing to operate such service, it was announced by Health Minister Arthur M. Nordmeyer, in the *New York Times*, July 1. It was stated that a salaried state medical service would be established if doctors wish to operate on that basis. Sixty-seven refugee doctors have received permits to enter the country and thirty-one are now practicing in New Zealand. It was reported that the government also proposes to establish a home nursing service and domestic aid service at the first opportunity.

Health and Sanitation in Vichy—A shortage of medical supplies in Vichy, France, are indicated in statements to the press, August 4. Castor oil, bismuth, horse serum, quinine and absorbent cotton are not available, bandages are mere improvisations; layers of absorbent paper supplanting the usual cotton. Several hundred thousand units of insulin donated by the United States in November 1942 served to lessen the critical need of the 30,000 diabetic persons in France. The increase in tuberculosis is attributed to the presence of the disease in repatriated prisoners, who, in view of inadequate hospital facilities are left in their homes thereby infecting their families. Lack of soap is a factor in the spread of certain diseases. Sheets in hotels are rinsed only in cold water and allowed to dry. Irons are not used because of need for fuel economy. At the Edvard Heriot Hospital in Lyons it was decided to use mutton tallow as a substitute for grease, after more than two months' delay because of red tape it was delivered to the hospital in the form of a 'huge lump of dirty crude suet'. Hospitals through necessity must refuse admittance to all but the most critically ill; even fracture patients are reluctantly accepted because limited food resources do not meet the length of stay of the average fracture patient. The Swiss people have been caring for many of the undernourished children who have been able to take advantage of their offer of summer vacations.

CORRECTION

Toxic Eruption Due to Amphetamine Sulfate—In the summary of the article with this title by Kauvar, Henschel and Ravin in *THE JOURNAL* August 14 page 1073 it was stated in the summary that "an atopic dermatitis eruption resulted from the ingestion of amphetamine sulfate and its analogue dextroamphetamine sulfate." This sentence should have read "an atopic dermatitis-like eruption resulted from the ingestion of amphetamine sulfate and its analogue dextroamphetamine sulfate."

Government Services

Dr. Heller Named in Charge of Division of Venereal Diseases

John R. Heller, Jr., P. A. Surgeon with the States Relations Division, U. S. Public Health Service, Washington, D. C. since April 1941, has been assigned in charge of the division of venereal diseases in the Office of the Surgeon General. He succeeds Dr. Raymond A. Vonderlehr, who has been named director of district number 6 of the public health service covering Puerto Rico and the Virgin Islands (*THE JOURNAL*, August 14, p. 1138).

Foreign Letters

LONDON

(From Our Regular Correspondent)

July 22, 1943

Centenary of the Fellowship of the Royal College of Surgeons

The centenary of the foundation of the fellowship of the Royal College of Surgeons has been celebrated by a reception given by the president and the council. The distinguished company included ambassadors of the allied nations, members of the government and many foreign surgeons whom the war has brought to our shores. The award of the honorary fellowship to the following foreign surgeons was announced: Sir Hugh Deane, Melbourne, Prof A T A Jurasz, Poland, Prof N Burdenko, chief surgeon of the Soviet army, Prof S S Yudin, Moscow, Col E C Cutler, Harvard, Prof W G Penfield, McGill, Prof E A Graham, St Louis, Prof R B Osgood, Harvard, Prof N S Shennstone, Toronto, Prof N Mahfouz Pasha, Cairo, Prof I W Brubner, Witwatersrand. Admitted to honorary fellowship at the reception were Col J M Holst, Norwegian army, Col J A Macfarlane, consulting surgeon to the Canadian army, Prof H C Naffziger, San Francisco.

In his address the president, Sir Alfred Webb-Johnson, said that the amenities of the college had been destroyed by the enemy and they were grateful for the great hall of Lincoln's Inn being placed at their disposal. He then turned to "praise famous men and our fathers that begot us." Of such were John of Arderne, Thomas Morstede, Wiseman, Vicary, Ranby, Cheselden, Pott, Abernethy, Astley Cooper, Bell, Hilton and Paget. Towering above all were John Hunter, the founder of scientific surgery, and the immortal Lister. Benjamin Brodie founded the fellowship, and the by-laws governing it were so well laid that they needed little revision during the hundred years. Referring to the prime minister, Winston Churchill, on whom the honorary fellowship had recently been conferred, he said that when the history of our time comes to be written he will be judged worthy of the tribute paid to Lister by the American ambassador, Mr Bayard: "It is not a profession, it is not a nation, it is humanity itself which, with uncovered head, salutes you."

A message was received from the king as visitor of the college. He sent congratulations and expressed satisfaction on the conferring of the honorary fellowship on distinguished surgeons from the dominions and allied countries. He trusted that the plans for the restoration of the unique museum will be carried out soon after the war. In his reply the president assured the king that the fellows will be untiring in their efforts to restore the museum, toward which they have received the most generous promises of help from all parts of the empire. The steps already taken to restore this greatest museum of anatomy and pathology in the world have been described in previous letters. Some of the losses due to bombing are irreparable.

War Troubles of the British Medical Journal

In the annual report of the council of the British Medical Association it is stated that the *Journal* has continued to appear regularly though the difficulties of production and distribution increase as the war goes on. Paper is severely rationed, and because the main part of each weekly issue of nearly forty-five thousand copies has to be sent to members, whose numbers are steadily growing, it is impossible to make any substantial economy by cutting the circulation. The only way to eke out

the ration is to use paper of less weight, to cut down advertisements and text and to print in smaller ranges of type. All these methods have been adopted and little more can be done except to trim the paper margins. The varied needs of the profession in wartime cannot be covered adequately in a journal with a large obligatory circulation by much less than half its peacetime number of pages. This seems to be understood by members, who have noticed other newspapers and periodicals shrinking in size year by year and employing every device to save paper and get more print on a page. It is perhaps less well realized that the number of articles submitted to the *Journal* is now as large as before the war and that the inflow of weekly correspondence has surpassed all previous experience. The task of selection is therefore harder and more invidious than ever. Meanwhile the Ministry of National Service has drawn away experienced workers from the editorial and business departments and from the printing works, and further staffing difficulties must be expected. The most that the council can promise is that everything possible will be done to produce a journal which maintains its place among the leading medical periodicals of the world and promotes the profession's war effort.

Food Changes Due to the War

Dehydrated cheese, mixed with potato flour and compressed into blocks, was among the new forms of food mentioned by Sir John Bodinnar, commercial secretary to the Ministry of Food, in describing the saving of precious shipping space by "putting food into battle dress." Last year we saved 41 million cubic feet of space by importing boned, molded and telescoped carcasses of meat, 22½ million cubic feet by importing dried instead of shell eggs, 1 million cubic feet by importing milk powder instead of canned condensed milk. These figures represent a saving of 750,000 ship tons. Other developments were a more compact form of importing bacon from the United States by using bales instead of wooden boxes, and using chests made of jute fiber instead of plywood for importing tea.

This season for the first time peas are being dehydrated. They keep well and are less bulky than canned peas and therefore more economical to transport. When water is added they appear like freshly gathered peas. Like dehydrated cheese, their production so far is earmarked for the fighting forces. So also are dehydrated potatoes prepared by a new process. All these new methods of treating foods have been introduced as part of the war effort but have considerable postwar possibilities.

Streptococcic Myositis

Gas gangrene is regarded as due to anaerobic spore bearing bacilli, which infect and destroy muscle. The war wounds in the Middle East have brought to light a rare condition, streptococcic infection of muscle in wounds, which has to be distinguished from ordinary gas gangrene as the treatment is quite different. Attention to this condition is drawn in the *Army Medical Department Bulletin* for June. From the autumn of 1941 to the autumn of 1942, not including the second battle of El Alamein, 19 cases were observed. The distinction of streptococcic myositis from ordinary gas gangrene rests on the following points: 1. Cutaneous erythema is usually well defined and there is more discoloration of skin than of muscle, in gas gangrene the opposite generally holds. 2. The discolored muscle is of coppery color but does not have the boiled and congealed appearance of typical gas gangrene, further, the muscle is alive and will react to stimuli. 3. The smell is neither so pungent nor so sweet as in gas gangrene. 4. Films of muscle stained by Gram's method show many streptococci and pus cells. In gas gangrene a few cocci may be found among the bacilli associated with clostridial gas gangrene, but the picture in streptococci

myositis is quite different in that the streptococci are either present alone or in much greater numbers than any other organisms. The anaerobic streptococci appeared to be an essential factor, but the accompanying organisms determined the exact clinical picture. These were found in every case, most often either ordinary aerobic *Streptococcus pyogenes* or *Staphylococcus pyogenes*. The *Streptococcus pyogenes* infections were the most acute and cutaneous erythema was a prominent feature. The *Staphylococcus pyogenes* infections were somewhat insidious, and a white boggy edema was often found. Five of the 10 patients died from a progressive toxemia, sometimes accompanied by streptococcal septicemia.

The essentials of successful treatment are large doses of sulfonamides locally and by mouth combined with conservative surgery, such as skin incisions and exposure of the affected muscle. Bad results have followed more radical treatment. Hence the great importance of distinguishing the condition from ordinary gas gangrene.

A Charter for Midwives

The concern felt at the falling birth rate has directed attention to the importance of skilled service in childbirth. There is a shortage of midwives. A Midwives Salaries Committee appointed by the Ministry of Health has presented its report which recommends that national scales of salary shall apply to certified midwives employed in hospitals, maternity homes or domiciliary service. Important proposals are also made as to uniform, accommodation, hours of duty, holidays with pay and sick pay. At present midwives deliver two thirds of the 600 000 babies born in England and Wales and act as maternity nurses under a doctor's direction at most of the remaining cases. Legislation during the present century has placed midwifery on a sound professional basis and has done much to improve the status of the midwife. Notwithstanding this the midwife has no protected uniform of her own. The provision of a national uniform would contribute to her public standing. On the whole the prospects of midwifery as a profession compare unfavorably with those of nursing. For some years there has been a shortage of midwives, and this has been aggravated by the war creating a vastly increased demand for nurses which has caused many midwives also qualified as nurses to take up this occupation. The committee recommended national scales of increased salaries which have been accepted. A pupil midwife will receive a salary of £200 for the first year, £225 for the second year and until she has passed her first examination, and £300 after she has passed until she has completed her training. A trained midwife will receive a salary which with emoluments will be worth \$1050 and will rise annually by increments of £25 to £1250. The higher positions of superintendent midwife, assistant matron and matron will receive more culminating in £2750.

Vitaminized Chocolate for Freed Europe

There is less chocolate for the public because a large part of the manufacturers have gone over to making vitaminized chocolate for distribution in Europe when freed. It will be specially for children from 7 to 14 years of age. It is being made in bars of 1 ounce weight which will provide the greater part of the day's requirements of vitamins A, B, C and D. Their efficacy has already been proved in Malta. When Dr J. C. Drummond, scientific adviser to the Ministry of Food visited Malta after its resistance to siege and bombing he found the nutrition of the children such that he recommended that supplies of vitaminized chocolate be sent. During the war many experiments have been made to discover the best medium for vitamin. Biscuits, sweets and spreads of all kinds have been tried and chocolate has been found the best for providing vitamins in a palatable and acceptable form. Vitaminized chocolate will not be on sale here but the War Office has ordered large quantities.

BUENOS AIRES

(From Our Regular Correspondent)

July 25, 1943

Attempt at Antiplague Vaccination with Living Bacteria

An outbreak ofylvatic plague appeared in Cordoba in the fall of 1940. Rodents were found to play an important part in the spread of the epidemic, which up to now has not been entirely controlled. Well organized brigades appointed by the National Department of Hygiene are carrying on an active campaign against plague. Dr J. K. Goobar vaccinated 30 persons of both sexes against plague (29 adults and a child aged 8 years). He used a vaccine of the Girard type, the same as that which was tried in Java and Madagascar. The vaccine used in Java and Madagascar did not cause any accidents, whereas both morbidity and mortality from plague were greatly diminished. The vaccine is prepared with a strain of *Pasteurella pestis* which was isolated by Girard from a patient with ganglionic plague in Madagascar. The virulence of the strain was attenuated by successive passages in nutrient agar at 22 C. A suspension of the living attenuated strain in isotonic solution of sodium chloride with a concentration of 1 billion bacteria for each cubic centimeter of the suspension was prepared and maintained at a constant temperature above 4 C and administered at a dose of 1 cc for adults and 0.5 cc for the child. The vaccine was well tolerated and followed by a mild local reaction with mild fever and, in some cases, mild axillary adenopathy. The president of the Provincial Department of Hygiene ordered the appropriate provincial and medical authorities to undertake a mass vaccination on the persons living in the endemic districts in the near future.

Conference on Tuberculosis in Peru

The first National Conference of Tuberculosis was recently held in Lima, Peru. Dr M. Espinoza Galarza, the president of the Peruvian Society of Phthisiology, presided. Topics discussed were indexes of infection, morbidity and mortality of tuberculosis in different regions of Peru, social factors involved in the development of the disease, clinical forms of tuberculosis in patients in dispensaries and hospitals, and surgery in pulmonary tuberculosis.

The incidence of infection was discussed in fourteen articles which were prepared with the reports of observation of 170 000 persons. The average index of tuberculous infection was 60 per cent for adults of either sex and 53 per cent for children from birth to the age of 16 years. The partial indexes of the three geographic zones of Peru are similar which shows that the Peruvian population is in a progressive and massive stage of the infection. There was an index of from 3 to 5 per cent of active tuberculosis in apparently normal persons. An average index of tuberculosis mortality could not be determined on account of local difficulties in obtaining the data. One can conclude from the reports of the three geographic zones of the country that the various factors of nutrition, housing, local crowding of the population, salary migration of the people and the local condition of hygiene and sanitation in the different zones are the causes of the degree of tubercularization in the country. The attention of the Peruvian phthisiologists was directed to the advisability of accepting the classification of the clinical forms of pulmonary tuberculosis presented by the members of the chair of phthisiology of the Faculty of Medicine of Lima. Resolutions were adopted (1) to establish a general board in charge of the national antituberculosis crusade with autonomic authority for the necessary technique and administrative steps (2) to organize centers for carrying on national x-ray photographic and tuberculin censuses for an early diagnosis of tuberculosis (3) to ask the proper authorities to

increase construction of hygienic and inexpensive houses using the fund which has been built up by the workers and employees, (4) to consider alcoholism a social scourge and a factor of importance in the development of tuberculosis, (5) to prepare some laws for improving both the quality and the quantity of milk, for controlling the sanitary conditions of stables and for supervising the health of cows, (6) to increase the functions of antituberculosis organizations for protecting children and the number of nutritional centers and antituberculosis hospitals, clinics and dispensaries, (7) to establish maternity hospitals for tuberculous mothers and nurseries for their children, (8) to increase the number of beds available for tuberculous patients in hospitals, (9) to establish the use of record books to be presented for the patients when medical care and medicine from dispensaries are wanted (10) to create new postgraduate courses of specialization in antituberculosis medical and surgical fields and to improve those which are already functioning, (11) to create an institute for phthisiologic researches, improving social work and giving dental care to those in need of it, (12) to ask for laws through which parents who abandon their children shall face punishment for social delinquency, (13) to improve the personnel concerned with the preparation of tuberculosis statistics, (14) to establish an insurance against tuberculosis, as it was advised to do it in the 1940 national antituberculosis week, and (15) to obtain the philanthropic, economic and moral aid of the people

Reticuloendothelial System in Malaria

Drs M A Maldonado and J R Monasterio recently lectured before the Society of Legal Medicine and Psychiatry of La Plata. They were mainly concerned with the role of the reticuloendothelial system in the result of malarial therapy. Malaria stimulates a reaction of defense of the reticuloendothelial system, which is shown by the appearance of monocyto-sis and the results of the congo red test and other similar tests. The results of malaria therapy depend on the degree of reticuloendothelial reaction. The authors carried on observations on several patients in the course of malarial therapy. They believe that the modifications of the blood constitution, the microscopic changes of Kupffer's cells and the microglial reaction on the one hand and the results of the red congo test and other similar tests allow one to evaluate the degree of defensive reticuloendothelial reaction in malarial therapy. They also discussed the possibilities of therapeutic application of the reticuloendothelial reaction in other diseases, such as leprosy and leukemia.

Cancer Mortality in Buenos Aires

Dr Angel H Roffo, head of the Instituto de Medicina Experimental para el Estudio y Tratamiento del Cancer, recently published statistics on mortality from cancer in Buenos Aires in relation to morbidity. There were 4,084 deaths from cancer in 1941, which represents 162.80 for each hundred thousand persons in the city. Cancer of the respiratory tract increased from 148 cases in 1926 to 742 in 1941. Dr Roffo believes that the increase depends on the atmospheric changes due to exhaust gases from cars and smoke from industrial plants. Cancer is more frequent in parts of the body exposed to the sun than in those which are protected by clothing. The highest figures are those for cancer of the nose (37.43), those for cancer of the forearm were 0.25.

New Hospital

The 750 bed Juan A Fernandez Hospital was recently opened in Buenos Aires at a cost of 4,000,000 Argentine pesos. There are sixteen operating wards. It is air conditioned. Portable microphones and amplifiers are available. There are several halls with a room accommodating 200 persons waiting for consultation.

Tuberculosis in Uruguay

Dr Armando Sarno is head of the Servicio de Lucha y Preservacion Antituberculosa of Uruguay. X-ray examinations of the thorax were carried out on 134,209 persons in Montevideo. Tuberculous shadows were seen in 13.4 per cent of the films. The frequency of tuberculosis in various districts of the city varied between 8 and 20.9 per cent. There are several antituberculosis centers, hospitals, clinics and colonies for tuberculous patients in the country, yet the distribution is uneven. Dr Sarno believes that in Montevideo no less than 3,000 beds for tuberculous patients should be available.

Congress of Industrial Physicians

The convention of industrial physicians which was organized by the Instituto Argentino de Seguridad took place recently at the headquarters of the Liga Argentina contra la Tuberculosis. The topics discussed were brucellosis, prevention of brucellosis, dermatosis in oil workers, importance of dermatology in industrial medicine, hypodermotrichosis, dermatitis caused by carrot juice and by pancreatic enzymes, heart diseases in relation to selection of workers and mercurialism.

Personals

Dr Ramon Carrillo was recently appointed to the chair of neurosurgery at the Faculty of Medicine of the University of Buenos Aires to fill the vacancy left by Dr M Balado, who died.—Dr Charles E Oberling of the Public Health Service of New York recently visited Buenos Aires.—Dr Rogelio Carratala was recently appointed president of the chapter of legal medicine of the Academia Latino-Americana de Neurologia, a member of the same academy in Brazil and a member of the American Council for Research on Problems of Alcohol.

Brief Items

The first Inter-American Congress of Roentgenology will be held in Buenos Aires during one of the last two weeks of October. The headquarters of the Committee on Organization is Calle Alsina 3317, Buenos Aires, Argentina.

Marriages

RANSOM RUSSELL BUCHHOLZ, Georgetown, Texas to Miss Virginia Barrere of Nashville, Tenn., at Columbia, S C, August 2

HENRY BAKER PERRY JR., Baltimore to Miss Lillie A Brown of High Point, N C, at Boone, N C, August 6

MAX K MOULDER, Nashville, Tenn., to Miss Marcella Grace Castle of Kansas City, Mo., at Dallas, Texas, June 27

CHARLES GORDON SMITH III, Rocky Mount, N C, to Miss Ethel Mervyn Jarvis at Lansdown, England, July 17

JULIUS KATZ, Grafton, Ill., to Miss Kathryn Kuhn of Fort Wayne, Ind., at Columbus, Ohio, August 11

RICHARD CULLER HORGER, Eutawville, S C, to Miss Mary Elizabeth Smith in Greenwood recently

BRODIE C NALLE JR., Charlotte, N C, to Miss Carolyn J Woolley in Maplewood, N J, June 26

HORACE MILTON DALTON, Norton, Va., to Miss Lalla Lee Laffitte of Estill, S C, August 10

LENORE VIRGIE LEE PATRICK to Mr Everett Chipman, both of Williamstown, Ky., August 21

CHARLES L TINKER to Mrs Mary B Sharp, both of New Philadelphia, Ohio, August 12

JEAN TODD STOOPS, Wabash, Ind., to Miss Margaret E Mohrley of Cincinnati, June 26

FRANK SMITH LOVINGOOD, Maryville, Tenn., to Miss Martha Ijams at Knoxville, July 17

ELLIS D PARKER, Laurel, Miss., to Miss Antoinette Marie Rivard of Detroit, July 18

THOMAS J McDONNELL, Sterling, Ill., to Miss Eileen O'Donnell of Chicago, August 7

Deaths

Aleš F Hrdlicka, noted anthropologist died at his home in Washington D C September 5, of heart disease.

Dr Hrdlicka was born in Humpolec, Bohemia March 30 1859. He graduated at the Eclectic Medical College of the City of New York in 1892 and the New York Homeopathic Medical College and Hospital in 1894. Subsequently he carried on surveys among the insane and other classes and made anthropologic expeditions to many countries.

In the interim of his service as associate in anthropology at the New York State Pathological Institute from 1896 to 1899, Dr Hrdlicka spent a year in the study of anthropology at the medical school and the school of anthropology at the Sorbonne in Paris. In 1903 he was appointed assistant curator of the division of physical anthropology at the National Museum or the Smithsonian Institution in Washington. From 1910 to his retirement in 1942 Dr Hrdlicka was curator.

Many awards went to Dr Hrdlicka during his career. Among his activities were his service as secretary of the committee on anthropology for the National Research Council 1917-1918. He was a life member of the American Academy of Arts and Sciences. In 1925-1926 he served as president of the American Anthropology Association and during 1928-1929 as president of the Washington Academy of Sciences. He was founder, president and life member of the American Association of Physical Anthropology and corresponding member of many European anthropologic societies. In 1927 he was Huxley medal lecturer in London on anthropology and related subjects.

Dr Hrdlicka had written extensively on his specialty. He was the founder of the *American Journal of Physical Anthropology*, serving as editor at the time of his death.

John Lincoln Rothrock @ St Paul University of Pennsylvania Department of Medicine Philadelphia 1888 professor emeritus of obstetrics and gynecology at the University of Minnesota Medical School Minneapolis where he had been clinical instructor in pathology, clinical instructor in pathology and gynecology, assistant professor of gynecology, associate professor of obstetrics and gynecology and professor, formerly professor of obstetrics and gynecology at the University of Minnesota Graduate School specialist certified by the American Board of Obstetrics and Gynecology. Inc member of the House of Delegates of the American Medical Association in 1921, from 1923 through 1926 and in 1928 member of the Central Association of Obstetricians and Gynecologists a founder and fellow of the American College of Surgeons assistant health commissioner in St Paul from 1896 to 1899 author of 'Ten Years of Obstetrics and Gynecology in Private Practice,' 1933 received the doctor of science from Gettysburg College in 1934 for many years on the staffs of St. Joseph's Hospital St. Luke's Hospital, Bethesda Hospital and the Ancker hospitals from 1921 to 1931 chief of the department of obstetrics and gynecology at the Wilder Dispensary and the Charles T Miller Hospital, where he died July 5 of periarteritis nodosa and acute atrophy of the liver aged 79.

Morrow Duncan Brown @ Denver Northwestern University Medical School Chicago 1900 member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological Rhinological and Otolological Society major in the medical reserve corps of the U S Army not on active duty and served with the same rank during World War I on the staffs of the Childrens Mercy Presbyterian St. Joseph's and St. Anthony hospitals, Denver, and the Evangelical Lutheran Sanitarium Wheat Ridge, Colo, and the Porter Sanitarium and Hospital at one time physician for the Denver and Rio Grande Railroad aged 65 died July 1 of coronary disease.

Stephen Hulbert Ackerman @ Major, U S Army retired Hollis N Y Columbia University College of Physicians and Surgeons New York 1911, served during World War I entered the medical corps of the U S Army as a captain in July 1920 retired in October 1928 under a special act was retired as a major in June 1930 formerly medical superintendent of the Fordham Hospital New York superintendent of the Coney Island Hospital Brooklyn, at one time associated with the U S Veterans Bureau Washington D C aged 57 died in the Brooklyn Hospital, July 2, of pituitary adenoma.

Reed Brinsmade Bontecou, Clifton Springs N Y College of Physicians and Surgeons New York, 1889, member of the Medical Society of the State of New York at one time secretary of the Rensselaer County Medical Society, served in the medical corps of the U S Army during World

War I formerly on the staff of the Marshall Sanitarium Troy at one time associated with the U S Veterans Bureau later known as the Veterans Administration in Boston and the U S Veterans Bureau in Springfield, Mass., aged 78, died, June 18, of cerebral hemorrhage.

Rufus Eldridge Applewhite, Winnsboro La Memphis (Tenn) Hospital Medical College 1913 member of the Louisiana State Medical Society formerly secretary of the Franklin Parish Medical Society served during World War I director of the Franklin Parish Health Unit and acting director of the Concordia Parish Health Unit, aged 55 died, May 3, in the Winnsboro Sanitarium of coronary occlusion.

Clarence John Bell, Wellfleet Mass College of Physicians and Surgeons Baltimore 1902 member of the Massachusetts Medical Society, chairman of the board of health for many years a member of the school board trustee of the Wellfleet Savings Bank, acting assistant surgeon U S Public Health Service on the staff of the Cape Cod Hospital, Hyannis, aged 66, died June 6, of angina pectoris.

Frank W Braley, Saranac Mich Detroit College of Medicine, 1897 member of the Michigan State Medical Society, formerly president of the school board and health officer, aged 81 died June 15 in the Blodgett Memorial Hospital Grand Rapids, of arteriosclerosis.

Laura Jane Brown, Glendale Calif Hahnemann Medical College and Hospital Chicago 1903 aged 78, died July 1, of carcinoma.

William A Bryant, Antonito, Colo Kansas City (Mo) College of Medicine and Surgery, 1921 member of the Colorado State Medical Society on the staff of the Community Hospital, Alamosa aged 51 died May 31, in St. Joseph's Hospital Denver of congestive heart disease.

Viola May Coe, Portland Ore Woman's Medical College Chicago 1890 aged 80 died May 27, of cerebral hemorrhage and heart disease.

Ernest Lee Collins, Tyro Miss (licensed in Mississippi in 1911) member of the Mississippi State Medical Association, aged 67 died June 13 of cerebral hemorrhage.

William M Copenhagen Jr, @ Helena Mont. University of Minnesota Medical School Minneapolis 1932 diplomate of the National Board of Medical Examiners formerly city health officer served on the staffs of St. Peter's St. John and Shodair Crippled Children's hospitals aged 37 died May 23 as the result of an automobile accident in November 1941.

John Christian De Fries, Thawville Ill Rush Medical College Chicago 1894 member of the Illinois State Medical Society aged 81 died recently of coronary heart disease and arteriosclerosis.

John Wesley Ferman Emlenton Pa Jefferson Medical College of Philadelphia 1904 aged 63 died June 18 of cerebral hemorrhage.

Samuel Isaac Fine @ New York Long Island College Hospital Brooklyn 1915 member of the staffs of the Bronx and Lincoln hospitals aged 54 died June 24 of myocarditis.

Cary Breckinridge Gamble Jr @ Baltimore University of Maryland School of Medicine Baltimore 1887 formerly professor of medicine at his alma mater served in France during World War I formerly medical referee for several insurance companies aged 80 a member of the staff of the Union Memorial Hospital where he died June 1 of arteriosclerotic heart disease and chronic bronchitis.

Henry Larkin Green @ Shreveport, La University of Pennsylvania School of Medicine Philadelphia 1914 medical examiner for the draft board on the staff of the Tri-State Hospital aged 63 died June 22 of coronary occlusion.

J Glenn Hemington, Uniontown Pa Cleveland Homeopathic Medical College 1901 member of the Medical Society of the State of Pennsylvania formerly medical director of Fayette County aged 69 died May 22 in the Uniontown Hospital of cerebral hemorrhage.

Wiley Calvin Kennedy Talmo Ga Atlanta Medical College, 1894 member of the Medical Association of Georgia aged 71 died May 20 of heart disease.

Edward J Konop Sawyer Wis Marquette University School of Medicine Milwaukee 1924 served during World War I recently resigned as an examiner for the Selective Service System aged 48 died in Sturgeon Bay, June 17, of acute yellow atrophy of the liver.

Ruth Almina Kreitz @ Cambridge Springs Pa Woman's Medical College of Pennsylvania Philadelphia 1933 school medical inspector member of the board of the Crawford

County Tuberculosis Society, member of the staff of the Merdville City Hospital, aged 34, died, June 15, of myocardial failure and chronic glomerulonephritis

John Milton Luther, New Florence, Pa., University of Pennsylvania Department of Medicine, Philadelphia, 1908, served on the staffs of the Passavant Hospital, Pittsburgh, and the Lee Homeopathic Hospital, Johnstown, aged 63, died, June 14, of coronary thrombosis

Reginald E. Macdonald, Virginia City, Nev., California Medical College Oakland, 1885, aged 81, died, June 13, in the Washoe County General Hospital, Reno, of myocarditis

Donald R. MacLeod, Wichita, Kan., Kansas City (Mo.) Homeopathic Medical College, 1899, aged 68, died, June 15, of carcinoma of the spinal cord

William John Nicholson, Centerville, Ala., Vanderbilt University School of Medicine, Nashville, Tenn., 1884, member of the Medical Association of the State of Alabama, president of the Bibb County Medical Society in 1887, served as probate judge of Bibb County for many years, aged 82, died June 18, of cerebral hemorrhage

Henry Clyde O'Roark, Portsmouth, Ohio, University of Louisville (Ky.) School of Medicine, 1926, member of the Ohio State Medical Association, served during World War I, on the staff of the Mercy Hospital, a member of the Portsmouth Rotary Club, aged 45, died, July 9, in the Veterans Administration Facility, Bay Pines, Fla.

Charles Oliver Rainey, Camilla, Ga., Atlanta School of Medicine, 1910, member of the Medical Association of Georgia, served as president of the Georgia Public Health Association, county health commissioner, aged 59, died, May 14, of cerebral hemorrhage

Alice Mary Ridge, Ogden, Utah, University of Michigan Homeopathic Medical School, Ann Arbor, 1909, member of the Utah State Medical Association, on the staff of the Thomas D. Dee Memorial Hospital, aged 66, died, June 9, of carcinoma of the pancreas

George Jacob Rubelman, Tecumseh, Neb., Rush Medical College, Chicago, 1880, member of the Nebraska State Medical Association, served as mayor of Tecumseh, county coroner, city physician, physician for the insanity commission and as a member of the school board, aged 89, died, June 2, of mitral insufficiency

John Francis Sabbia, Brooklyn, Fordham University School of Medicine, New York, 1918, member of the staffs of the Kings County, Shore Road and Victory Memorial hospitals, aged 47, died, June 19, of coronary thrombosis

Sylvester Wright Saunders, San Diego, Calif., American Medical College, St. Louis, 1877, aged 91, died, June 22, of senility

Josiah P. Saye, Ball Ground, Ga., University of Georgia Medical Department, Augusta, 1883, aged 83, died, May 21, of a fractured hip received in a fall

Walter Gustav Adolph Schulte, Salt Lake City, University of Colorado School of Medicine, Denver, 1907, member of the House of Delegates of the American Medical Association in 1934, member of the American Urological Association, fellow of the American College of Surgeons, specialist certified by the American Board of Urology, Inc., on the staff of the Holy Cross Hospital, aged 64, died, June 8, of coronary occlusion

Alonzo Covert Smith, Wooster, Ohio, University of Michigan Medical School, Ann Arbor, 1915, a charter member of the Rotary Club, past president of the Wayne County Medical Society, president and chief surgeon at the Kinney Memorial Emergency Hospital, aged 55, died, July 10, of coronary thrombosis

Simon Harris Smith, Atlanta, Ga., Emory University School of Medicine, Atlanta, 1928, aged 41, served on the staffs of the Georgia Baptist Hospital, Piedmont Hospital and the Emory University Hospital, where he died, June 3, of Hodgkin's disease

Harry Clifford Stillwell, Rahway, N. J., Jefferson Medical College of Philadelphia, 1925, specialist certified by the American Board of Radiology, Inc., medical examiner for

the public schools of Rahway, formerly city physician, president of the staff of the Rahway Hospital, aged 40, died, June 15, in Macon, Ga., of a self-inflicted bullet wound

Eugene Finch Talbott, Grinnell, Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1895, member of the Iowa State Medical Society, fellow of the American College of Surgeons, served on the staff of St. Francis Hospital, aged 69, died, June 24, of coronary thrombosis at his summer home near Jenkins, Minn.

William De Alton Towsley, Syracuse, N. Y., University of the City of New York Medical Department, 1881, member of the Medical Society of the State of New York, at one time coroner of Oswego County, member of the staff of the Crouse-Irving Hospital, aged 86, died in the Marcy Hospital, June 9, of arteriosclerotic heart disease

John Cox Wall, Eastman, Ga., Atlanta College of Physicians and Surgeons, 1907, member of the Medical Association of Georgia and formerly councilor of the Third District, member of the Southeastern Surgical Congress and the American College of Chest Physicians, fellow of the American College of Physicians, also a pharmacist, owner of the Clinic Hospital, aged 60, died, May 18, of heart disease

Harry Hugh Wilson, Norman, Okla., Fort Worth School of Medicine, Medical Department of Fort Worth University, 1896, formerly medical superintendent of the Western Oklahoma Tuberculosis Sanatorium, Clinton, aged 76, died, June 4, in a hospital at McLester of pneumonia

William Townes Wimbish, Petersburg, Va., University of Virginia Department of Medicine, Charlottesville, 1896, aged 68, for many years on the staff of the Central State Hospital, where he died, June 4, of arteriosclerotic heart disease

Isaac Dix Winston, Sturgis, Ky., University of Nashville (Tenn.) Medical Department, 1900, member of the Kentucky State Medical Association, formerly local surgeon to the Illinois Central Railroad Company, a director of the Farmers State Bank, aged 69, died, June 25

Charles B. Woodley, Kinston, N. C., Bellevue Hospital Medical College, New York, 1886, aged 82, on the staff of the Memorial General Hospital, where he died, June 19, of myocarditis

Willis George Youens, Columbus, Texas, University of Texas School of Medicine, Galveston, 1907, served in the medical corps of the U. S. Army during World War I, health officer of Colorado

County for many years, formerly camp physician for the Civilian Conservation Corps stationed at Phoenix, Ariz., for many years local surgeon for the Southern Pacific Railroad, aged 59, died recently of coronary thrombosis

CAPT. ELPHEGE A. M. GENDREAU
1888-1943, M. C., U. S. NAVY

KILLED IN ACTION

Elphege Alfred Mailliot Gendreau, Medical Director, Captain, U. S. Navy, Washington, D. C., Georgetown University School of Medicine, Washington, 1914, Navy Medical School, 1916, commissioned a lieutenant, junior grade, in the medical corps of the U. S. Navy in April 1916, with a previous service of eight months in the medical reserve corps, advanced through the various grades to that of captain in August 1939, had served aboard the U. S. ships *Sacramento*, *Boreas*, *West Virginia*, *Glacier*, *Charleston* and the *Relief*, served in the Philippine Islands and in Haiti with the Public Health Service, and at many naval stations including the Naval Medical School, Washington, D. C., Receiving Station, San Francisco, Receiving Station, Hampton Roads, Va., and the Navy Yards at New York and Norfolk, Va., fleet surgeon on the staff of the Commander-in-Chief, Pacific Fleet, since June 1941, fellow of the American College of Surgeons, held the Mexican Service Medal, the Victory Medal with Atlantic Fleet Clasp, the Navy Expeditionary Medal, 1931 and a decoration from Haiti, the Bureau of Medicine and Surgery named Gendreau Circle on the reservation of the new U. S. Naval Hospital, Dublin, Ga., in honor of his memory, killed in action in the South Pacific, July 21, aged 55

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—The notices of judgment are issued under the Food Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D A I and foods F D A I. The abstracts that follow are given in the briefest possible form: (1) the name of the product (2) the name of the manufacturer, shipper or consigner (3) the date of shipment (4) the composition (5) the type of nostrum (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

A B D G Capsules Improved (After repackaged in part and labeled Hain Abdege Improved Vitamins.)—International Vitamin Corporation Brooklyn Shipped July 11 1941. Adulterated and misbranded because the label represented to contain 200 U S P units of vitamin B₁ per capsule it contained not more than 13 such units per capsule. Misbranded for the same reason. Also adulterated and misbranded under the provisions of the law applicable to food as reported in F D A J 3721—[D D A J F D C 566 November 1942]

Acetandyne Pain Tablets—W. B. Goebel trading as Botanical Medicine Company Kannapolis N C Shipped between June 7 and 10 1940. Composition no more than 0.99 grain of acetanilid and no less than 279 grains of aspirin per tablet. Adulterated because their strength differed from or their quality fell below the representation that each tablet contained 2 grains of acetanilid and 1 grain of aspirin. Also misbranded for this reason and because label failed to bear adequate warnings against unsafe dosage or methods or duration of administration necessary for protection of users and because wording on label "Pain Tablets" pains caused by menstrual disturbances" men- strual pains was false and misleading in representing the product to be efficacious in treating pains caused by menstrual disturbances whereas they were not—[D D A J F D C 476 September 1942]

Adiron—Lawrence Laboratories Chicago Shipped between Feb 5 and March 7 1941. Composition each tablet contained an iron compound equivalent to approximately 0.7 grain of metallic iron and 67 U S P units of vitamin A. Adulterated because its strength differed from and quality fell below that which it was represented to possess namely 1200 U S P A units of vitamin A per tablet. Misbranded because of label misrepresentations of vitamin strength and false claim. This core is the concentrate of the vitamins equivalent in vitamins A and D to one-half tea spoonful of fresh U S P Standard cod liver oil. Also misbranded because of false and misleading label representations that the product would be efficacious in treating nutritional (secondary) anemia make new blood and improve and maintain the health. Further misbranded and adulterated under the law applicable to foods as reported in F D A J 2986—[D D A J F D C 567 November 1942]

Cravex—Plant Products Company Inc Burbank Calif Shipped Feb 21 1941. Composition essentially calcium and manganese compound including phosphates with caffeine and milk sugar. Misbranded because labeling did not give proper directions for use since those that the package did bear were not adequate for the treatment of alcoholism for which the product was advertised. Further misbranded because labeling was false and misleading since the name Cravex was interpreted to mean treatment for craving for alcohol whereas the preparation did not constitute adequate treatment for that condition—[D D A J F D C 559 November 1942]

Crawford's Formula 53 with Vitamin E—Walter Bopp Eagle Rock Calif and Crawford Foods Inc Los Angeles Shipped July 18 1940. Composition tablets containing plant materials largely alfalfa (lucerne) leaf and stem tissues with smaller amounts of other plant materials including tomato seed anise fennel capsicum celery seed a leafy material such as parsley and yeast. Misbranded because false representation in labeling to be efficacious in building blood supplying the necessary vitamins and minerals to the blood stream for restoring normal functions of the body mechanism maintaining tone of sacral nervous system helping preserve the sex power and high vitality through building up the entire glandular system benefiting cases of pale and livid complexion dry skin discolored gums transparent and waxy ears habitually cold feet decaying teeth pyorrhea and some other things besides relieving arthritis heart disease degenerative disorders and bladder liver and kidney troubles—[D D A J F D C 441 September 1942]

DPS Formula No 54—Dartell Laboratories Los Angeles Shipped between July 7 and Aug 20 1941. Adulterated because its strength differed from and quality fell below that which it was represented to possess namely 1000 International Units of vitamin A 700 U S P A units of vitamin D and 100 International Units of vitamin C. Also misbranded for that reason and because of misrepresentations on

label that product would be useful in treating hyperacidity pericarditis low blood calcium most types of indigestion pregnancy lactation soft teeth and bones respiratory disorders asthma sinusitis and tuberculosis. Also adulterated and misbranded under provisions of law applicable to food as reported in F D A J 2978—[D D A J F D C 442 September 1942]

Germania Herb Tea—Germania Tea Company Minneapolis and Consolidated Drug Trade Product Inc Chicago Shipped between Jan 15 and 22 1941. Composition senega leaves about 40 per cent and smaller proportions of other leaves bilberry seed stems and flowers including arnica flowers yarrow leaves and seed and cyanus flowers. Misbranded because direction in accompanying booklet to drink this tea with meals as needed for a few weeks were not appropriate for an article of its composition and hence inadequate because aforementioned bile and a separate leaflet represented that use of the tea would give the consumer a normal healthy and beautiful figure and that the product would be effective for relieving many bodily aches and pains would give regular elimination for a healthy stomach would be efficacious for stomach heartburns sour stomach vomiting loss of appetite and restlessness among many other conditions. Further misbranded because label did not give the common or usual name of each active ingredient or indicate which of the plant materials that it mentioned are physiologically or therapeutically active—[D D A J F D C 442 September 1942]

Gid Granules—No 1 and No 2—Eberly Williams Manufacturing Company Chicago Shipped between April 9 and 17 1941. Composition No 1—essentially the mucilaginous part of psyllium seed with karaya gum sodium bicarbonate in proportions varying from 1.2 per cent to 8.2 per cent calcium carbonate in proportions varying from 0.79 per cent to 9.2 per cent a phosphate a sulfate and sugar. No 2—essentially the mucilaginous part of psyllium seed with karaya gum yeast and sugar. The No 1 was misbranded because label falsely claimed that 9 per cent of the product was calcium carbonate and another 9 per cent was sodium bicarbonate that the mixture was scientifically prepared so as to be of value in treating minor irritations of the stomach and upper intestines. The No 2 was declared misbranded because of false label claims for its alleged value in treating inflammation of the lower intestine and gastric constipation. Both products misbranded because represented in accompanying circular as efficacious for relieving distressing symptoms in many cases of stomach disorders headache pleurisy colitis and liver and gall deficiencies no due to infection—[D D A J F D C 443 September 1942]

Gly Cas—Gly Cas Medicine Company Muncie Ind Shipped Nov 25 1940. Composition capsules each containing about 4.3 grains of plant material including aloe with a small amount of glycerin. Misbranded because label failed to warn sufficiently against unsafe dosage or methods or duration of administration such as are necessary for protecting the users or to caution the purchaser that continual or frequent use of the product might result in dependence on laxatives to move the bowels. Further misbranded because label falsely represented it as efficacious in treating muscular aches and pains poor digestion night terrors dizziness nervousness loss of pep and energy and some other conditions. Also misbranded because accompanying circular falsely claimed that Gly Cas contained no harmful drugs whereas the government contended that it was capable of causing harm. Misbranded finally because represented to have been on the market for twenty five years or more whereas it was essentially a preparation of aloe—a drug whose properties had been known for centuries and because the label statement "Compound of cinnamon aloe glycerin and licorice" did not indicate what was really the active ingredient—[D D A J F D C 444 September 1942]

Shores Special Formula Tablets—Shores Company Inc Cedar Rapids Iowa Shipped between Dec 12 1939 and April 14 1940. These tablets were sold under three separate designations C T C T and S C Pink. Tablets in each group adulterated and misbranded in that their strength differed from or quality fell below that which they purported to possess namely C T was represented to contain 10 grains each of calcined magnesia and bismuth subnitrate whereas the actual amounts were respectively not more than 8.86 and 8.48 grains each. C T tablet was represented to contain kamala and extract of kamala equivalent to 9 grains of kamala and to contain 1/2 grain of nicotine whereas the correct figures were respectively 8.1 grains of kamala and only 0.21 grain of nicotine. The S C Pink tablets purported to contain 1 grain of calcium iodized per tablet whereas the actual amount was no less than 1.95 grain—[D D A J F D C 446 November 1942]

Williams Formulas (Regular and Strengthened)—Williams S L R Laboratories Milwaukee Shipped July 26 1940. Composition Regular—essentially Rochelle salt (21.5 grains per fluid ounce) methanamine (5.2 grains per fluid ounce) iron and ammonium citrate (2.4 grains per fluid ounce) alcohol (3 per cent) water and extracts of plant drugs including a laxative one with aux vomica and capsicum. Strengthened—essentially the same as the Regular except that the three ingredients named were given respectively as 0.2 grains 0.5 grains and 3.8 grains per fluid ounce and the alcohol was given as 2 per cent. Misbranded because label directions were too general and hence unsatisfactory for articles of such composition in that they left too much to be left to judgment. Further misbranded because label failed to warn sufficiently against unsafe dosage in that they did not caution the user against continued use of the article might result in dependence on laxatives. Misbranded further because label of the Regular form represented that the product would provide iron for the blood and an alkaline for excess stomach acid and would be efficacious in treating constipation dizziness nausea and some other things and would help in bringing the system to a greater enjoyment of life and that the "S" strengthened form was a greater source—[D D A J F D C 444 September 1942]

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[EDITORIAL NOTE—These abstracts differ from other abstracts of Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they deal with nostrums which were misbranded because their labels failed to carry adequate warnings against giving them to children or using them in those pathologic conditions in which they might be dangerous to health, or caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Floracubes—Eugene H. Hunter trading as Floracube Company, Los Angeles. Shipped March 9, 1940. Composition (claimed): "Floracubes contain per average dose (16 boxes) less than 2 grains each of calcium carbonate, sodium bicarbonate chlorides, podophyllum magnesium, phenolphthalein oil of juniper, boron buchu, sodium benzoate, creosote iron and dextrin. Also mineral oil and jelly, agar and celluloses sugar, artificial color and flavor combined with free oxygen hydrogen and Ultra Violet. The above ingredients are combined with water under a special process to change their form and action to meet the requirements of Floracubes. (Additional ingredients present, less 1 Gr.) Manganese, iron, nitrates, fluorides, arsenates, sulphates, calcium and silica." Misbranded because foregoing claims give false impression that the product "derived its physiological activity in important respects by reason of its lubrication bulk, alkaline and germicidal qualities that it was nonirritating in action and might safely be used over a long period of time and that it contained the ingredients listed in significant amounts and that these ingredients were combined with water under a special process which changed their form and action whereas it derived its physiological activity practically if not entirely, from the ingredient phenolphthalein, which is irritating, it was not germicidal and could not be used over a long period of time without risk of injury and it did not contain the ingredients listed in significant amounts, since it contained no appreciable amount of any of the ingredients iron, boron, manganese, fluoride, sodium bicarbonate, calcium as calcium carbonate, or sodium benzoate, and the ingredients were not combined with water under a special process which changed their form and action." Also misbranded because label did not give name and place of business of manufacturer, packer or distributor, or an accurate statement of the quantity of the contents prominently placed thereon. Further misbranded because fabricated from two or more ingredients and these were not listed under their common names on the label, which likewise did not indicate that phenolphthalein was the only important active ingredient. Finally, it was misbranded because label failed to give adequate directions for use and caution against giving it to children or using it in those pathologic conditions wherein it might be dangerous to health, or to warn against unsafe dosage or methods or duration of administration, for protection of users, since labels did not inform purchasers that employment of this treatment in cases of abdominal pain, nausea, vomiting or other symptoms of appendicitis might result in serious injury and that frequent or continued use might cause dependence on a laxative.—[D D N J, F D C 552, November 1942]

Heads Up Headache Powders—Smith Brothers Drug Company, Greensboro, N. C. Shipped Dec 10, 1940. Composition: the average powder contained 4.68 grains of aspirin, 6.62 grains of sodium bromide and 0.57 grain of phenolphthalein. Adulterated because strength differed from that represented, since each powder contained materially more of the several ingredients than amounts declared on label. Misbranded for the same reason and because of false and misleading label representations that use of this product would enable one to brace up or "go smiling thru" when suffering from any of the various disorders mentioned on label. Misbranded further because label claim, "contains no acetanilid, harmful or habit forming drugs," was false and misleading, since the mixture might cause potentially harmful effects and was not essentially different from or safer than various other products on the market or safe under all conditions, and actually did contain potentially harmful and habit forming drugs. Misbranded, also, because the term "Acidum Acetylsalicylic" is not the common name for aspirin and because label did not give adequate directions for use. Finally, misbranded because label did not adequately warn against use in those conditions wherein it might be dangerous to health or caution the user that it should not be taken when symptoms of appendicitis, such as nausea, vomiting or abdominal pain, were present, or that frequent or continued use might result in dependence on laxatives.—[D D N J, F D C 446, September 1942]

Mackenzie Cold and Grippe Tablets—C. E. Jamieson and Company, Detroit. Repackaged by Guy, Inc., Seattle. Shipped March 19, 1941. Composition: essentially acetanilid (0.94 grain per tablet), caffeine, aloin, atropine sulfate and capsicum. Misbranded because labeling failed to warn sufficiently against use by children or in those pathologic conditions wherein it might be dangerous to health, such as cases involving nausea,

vomiting, abdominal pain or other symptoms of appendicitis, and to caution against unsafe dosage or methods or duration of administration, for protection of users, since frequent or continued use of this acetanilid containing product might cause serious blood disturbances, anemia or collapse and its use might result in dependence on a laxative. Further misbranded because label recommendation as a treatment for a feverish condition, coryza, hay fever, rhinitis, influenza and some other things was false and misleading because it was not an adequate treatment for those conditions. Misbranded also because each tablet did not contain 2 grains of acetanilid as claimed.—[D D N J, F D C 553, November 1942]

Pieridine—C. F. Breitenbach (Mucine Company), Chicago. Composition: essentially picric acid and eucalyptus oil incorporated in wool wax (lanum). Misbranded because label failed to bear name and place of business of manufacturer, packer or distributor, since designation "Amsworth Specialty Co., Kansas City, Mo.," did not make clear this concern's connection with the product. Further misbranded because label did not give the common or usual names of active ingredients or the quantity of each. Also misbranded because labeling failed to warn against use by children, or in those pathologic conditions in which its employment might be dangerous to health, or caution against unsafe dosage or methods or duration of administration, for protection of user.—[D D N J, F D C 436, September 1942]

Rogers Headache Soda—Rogers Drug Company, Memphis, Tenn. Shipped Nov 7, 1940, and Feb 4, 1941. Composition: chiefly acetanilid and not soda as name suggested. Misbranded because of false label statement that each powder contained 2½ grains of acetanilid, whereas the amount of this drug was not more than 1.9 grains per tablet. Further misbranded because label did not bear adequate directions for taking and sufficient warning against use by children, or in those pathologic conditions wherein it might be dangerous to health, or caution against unsafe dosage or methods or duration of administration for protection of users.—[D D N J, F D C 453, September 1942]

Sunshine Brand Powders—Lavoine Drug Company, Worcester, Mass. Shipped Oct 5, 1940. Composition: acetanilid only ingredient reported. Adulterated because each powder purported to contain 2 grains of this substance, whereas the actual amount was approximately 3.158 grains. Misbranded because of absence of label warning against unsafe dosage or methods or duration of administration in a manner necessary for protection of users, since frequent or continued use might cause serious blood disturbances, anemia or collapse. Further misbranded because potentially dangerous if administered to children, though label did not so warn. Also misbranded because package did not bear a label giving accurate statement of quantity of contents in terms of weight or numerical count.—[D D N J, F D C 551, November 1942]

Council on Medical Education
and HospitalsINTERN TRAINING FOR JUNIOR AND
SENIOR MEDICAL STUDENTS

Hospitals approved for intern training will not lose their approved status if they accept for internships medical students who are now in the junior or senior classes at the following medical schools:

Bowman Gray School of Medicine, Winston-Salem, N. C.
University of Utah School of Medicine, Salt Lake City
Medical School of Southwestern Medical Foundation, Dallas, Texas

Bowman Gray and Utah have long been approved schools of basic medical sciences. Recently they have expanded into four year schools. Bowman Gray now has junior and senior classes in session, and Utah will soon start a senior class. Both these schools will be visited by representatives of the Council in the near future to consider transfer of these schools from the list of approved schools in the basic sciences to the list of approved four year medical schools.

The Council has ruled that, on graduation, present juniors and seniors at the Medical School of Southwestern Medical Foundation shall be considered as if they had graduated from an approved medical school. This school will also be visited by the Council's representatives before the end of the year to consider possible full approval of the entire four year program. Should the school be included on the Council's approved list, the work of all students in good standing at the school at the time of the visit will be fully accredited.

In the meantime it is entirely satisfactory for approved hospitals to accept interns from these schools. Graduates of schools now on the approved list will in no way injure their records by accepting internships in such hospitals.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice Alleged Negligence in Treatment of Eye Injury—In the course of his employment the plaintiff suffered an eye injury, the exact nature of which the reported opinion does not make clear. He was attended by the defendant an eye, ear, nose and throat physician for about three months. The treatment administered by the physician 'at first consisted of atropine to dilate the pupil, hot applications, and injections of French protein. During the latter stages of the treatment butyn was prescribed for the relief of pain. Treatments were administered either by the physician by his office assistant under his directions and occasionally in his absence, and by the patient himself at intervals and in quantities prescribed by the physician. About three months after the industrial accident, the plaintiff's physical condition suddenly grew worse. He lost weight rapidly, his eye pained him severely, sores appeared over his face, his ear became abscessed and he developed stomach trouble. He consulted another physician who enucleated the eye. Subsequently the patient brought suit against the defendant physician, contending that his eye should have been enucleated immediately after the accident and that the treatment administered to him by the physician was not in the exercise of reasonable care and skill, and caused the subsequent ailments and suffering that befell him. He also alleged that the physician was guilty of malpractice (1) in authorizing and permitting his assistant who was neither a physician nor a registered nurse to treat him by probing his eye and giving him injections and (2) in prescribing medicines for self administration. The trial court directed a verdict for the physician, and the patient appealed to the circuit court of appeals fifth circuit.

It is the law in Georgia, said the circuit court of appeals, the state in which the treatment in question was administered that a practicing physician must bring to the exercise of his profession a reasonable degree of care and skill, and any injury resulting from a failure to exercise such care and skill is a tort. The record in this case is wholly lacking in evidence, expert or otherwise, to the effect that the treatment administered by the defendant physician was not in the exercise of reasonable care and skill and was not in accordance with approved medical practice. There is no evidence of any kind indicating that the patient's varied physical ailments were, or were likely to be, the result of the course of treatment undertaken by the physician. The sense of the testimony of the physician on examination in the trial court as an adverse witness was that the treatment given to the patient conformed in all respects to standard medical practice and that none of the ailments from which the patient suffered before the eye was

enacted could or did result from the treatment administered to him by the physician. His testimony was not contradicted, and it is the only evidence in the record relating to whether or not reasonable care and skill was exercised and whether or not a standard course of treatment was pursued. The evidence indicates that the physician's assistant was permitted to give the patient injections of French protein, to place hot applications on his eye and to administer atropine under the direction of the physician or in his absence, but it is clear that these ministrations were not such as required greater professional training than the assistant, by virtue of seventeen years of experience in the employ of the physician, was fully competent to administer.

The judgment in favor of the physician was affirmed—*Stoltz v. Crawford*, *Crawford v. Stoltz*, 131 F. (2d) 101 (1942).

Malpractice Statute of Limitation Does Not Begin to Run Until Cessation of Treatment—The defendant dentist on July 15, 1938, attempted to extract one of the plaintiff's lower third molars. After the extraction the socket of the extracted tooth bothered the patient, and about ten days later the patient returned to the dentist for treatment, as the socket was infected and exuded "much greenish pus." The dentist flushed out the infected area, but the socket continued to bother the patient and his condition became progressively worse. He returned for further treatments two or three times monthly until Oct. 20, 1939. The dentist continued to flush out the infected area but never had a roentgenogram taken to ascertain the cause of the trouble. A roentgenogram taken by another dentist about Oct. 20, 1939, disclosed two roots of the extracted tooth in a highly infected area surrounding the tooth socket. The roots were subsequently extracted by another dentist. Later, on Sept. 30, 1940, the patient sued the dentist for malpractice. An Oregon statute (the state in which the tooth was extracted) requires a suit for malpractice to be instituted within two years after "the cause of action shall have accrued." Agreeing at first with a contention of the dentist that the cause of action, if any, accrued at the time of the extraction of the tooth, July 15, 1938, and that the statute required suit to be instituted within two years thereafter, the trial court, in effect, dismissed the action on the ground that it had not been timely instituted. Later, however, the court on more mature reflection granted a new trial because it concluded that the negligence, if any, of the dentist was a continuing tort, that the cause of action did not accrue and the statute of limitations did not begin to run until the dentist ceased his treatment, namely, on Oct. 20, 1939, and that the suit having been started in September 1940 had been started timely. The dentist then appealed to the Supreme Court of Oregon.

The sole question involved in this appeal, said the Supreme Court, is whether the action has been commenced within two years after the accrual of the cause of action. The dentist argues that the cause of action accrued July 15, 1938, when the tooth was extracted, but the fallacy in his contention lies in an assumption that no continuing tort is involved. The duty and obligation of the dentist to his patient did not end on the partial extraction of the tooth. True, the mere fact in itself that the lower third molar was broken or crushed in extraction is not evidence of negligence. Dentists, like physicians and surgeons, are not guarantors of good results. A dentist is obliged only to exercise reasonable care and skill in the treatment of his patient. As to what constitutes reasonable care and skill—that is determined by the degree of care and skill ordinarily exercised by members of his own profession in similar places. The evidence in this case fails to disclose negligence in the original extraction of the tooth. It is common knowledge that an impacted wisdom tooth is difficult to extract and the operation often results in breaking parts of the roots. A dentist's work is not completed, however, by a partial extraction. The negligence here is really predicated on the failure to exercise due care and skill in diagnosing the cause of the plaintiff's trouble and in permitting the broken parts of the roots to remain in the tooth socket. Had the dentist taken or procured a roentgenogram it is reasonable to assume that there would have been no difficulty in diagnosing the case.

That the negligence of the dentist, if any, constituted a continuing tort the court regarded as a settled question by reason

of *Shivers v. Chamberlain*, 126 P. (2d) 28, which it had decided earlier in the year. In that case the gravamen of the plaintiff's cause of action was the alleged failure of the defendant specialist to diagnose and treat a case of glaucoma. The treatment extended over a year's time from month to month. It was urged there, as here, that the action was barred by the statute of limitations, but the court said:

This continued treatment, when shown to have been based upon a mistaken diagnosis and not of a character employed by the medical profession in dealing with cases of glaucoma, constituted a continuing tort causing the statute of limitations to start only when such treatment ceased.

The alleged negligent treatment of the dentist, continued the court, must be considered as a whole. The patient was not obliged to split his cause of action. The continued negligent treatment constituted but a single cause of action. Where the tort is continuing, the right of action is continuing. In the instant case there was a continuing duty of the dentist to exercise due care and skill in diagnosing the cause of the infection surrounding the tooth socket. As was said by the Supreme Court of Utah in *Petcler v. Robison*, 81 Utah 535, 17 P. (2d) 244:

Here the defendant undertook to treat the plaintiff for a throat affliction. From the time he undertook to treat the case until he ceased to treat it he, as alleged, did so in a negligent and unskillful manner. As alleged, the treatments were not separate and distinct acts, separate and distinct causes of action. They constituted an entire course of treatment of a case undertaken by defendant to be treated by him, and the whole thereof constituted but one cause of action. *Green v. Michigan Cent. R. Co.*, 168 Mich. 104, 133, N. W. 956, Ann. Cas. 1913C, 98, and notes on page 101. From the averments of the complaint, we think it should here be said, as was said in the case of *Sly v. Van Lengen*, supra, that the tort was a continuing one, and, where the tort is continuing, the right of action is also continuing.

The rule that the statute of limitation runs from the last date of the continuous negligent treatment is just and equitable. A rule to the contrary would often result in miscarriage of justice and would penalize a patient who, under continuous treatment, assumes that due care and skill will be exercised. Some courts hold that it is a harsh rule which precludes an injured patient from maintaining an action at a time when it was impossible to know that any existed. *Huysman v. Kirsch*, 6 Cal. (2d) 302, 57 P. (2d) 908.

The court accordingly affirmed the order granting a new trial to the patient—*Hotelling v. Walther*, 130 P. (2d) 944 (Or., 1942).

Current Medical Literature

AMERICAN

The American Library lends journal to member of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1944 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reproductive rights are the property of author and can be obtained for permanent possession only from them.

Pneumonia Due to *Streptococcus Viridans*—Solomon and Kalkstein describe 5 cases of atypical pneumonia in which *Streptococcus viridans* appears to have been the etiologic agent since it was recovered from sources other than the sputum. The following features suggest that pneumonia was due to *S. viridans*: (a) a prolonged severe course with a high mortality rate; (b) severe pleuritic reaction with serous effusion; and (c) failure of response to chemotherapy. Atypical pneumonia not responding to chemotherapy may be caused by *S. viridans*. A careful search for this organism should be instituted from the blood and pleural fluid as well as the sputum.

Pneumococcal Pneumonia: Sputum Examination—Frisch and his associates present data concerning the sputum count as a means of selecting therapy and a means of evaluating control of dosage of both serum and the sulfonamide drugs in patients with pneumonia. The treatment of pneumococcal pneumonia was individualized by dividing the cases into three major prognostic groups according to the number of pneumococci in Wright stained smears of rusty sputum. The cases in the first group represented approximately 50 per cent of the total admissions and were classed as relatively mild on the basis of sputum counts of 10 or less during the course of the disease. Over 95 per cent of these recovered with supportive therapy and with small doses of serum or with sulfonamides. Although the low fatality rate of 2 per cent was not appreciably altered by sulfonamides the pneumococci were more effectively prevented from multiplying and a more rapid defervescence was induced. The patients in the second group represented approximately 35 per cent of the total admissions and were classed as moderately ill on the basis of sputum counts between 11 and 35 per field. By decreasing the dosage when

a therapeutic response was elicited in the sputum, the total amount of sulfonamide administered was significantly reduced without affecting the final fatality rate. The last group with sputum counts over 35 included only 15 per cent of the total cases but was responsible for 70 per cent of the deaths. The sodium salts of the sulfonamides in large doses intravenously were the most effective therapeutic agents. Supplementary serum proved to be of no additional value in the most severe cases with sputum counts exceeding 50 per field.

Contractions of Human Uterus During Menstrual Cycle—Henry and Browne studied one or more cycles in 4 women with normal ovarian and uterine function. The studies included pregnandiol assays, endometrial biopsies and uterine tracings. A fifth woman was completely studied except that urinary assays were not done every day, a sixth whose cycles were abnormal to the extent that she was unable to conceive was also studied and a seventh had tracings and biopsies done in one cycle but no pregnandiol assays were made. In each the uterus contracted more strongly and was much more greatly affected by posterior pituitary injection in the presence of the corpus luteum than during the follicle phase. An artificially produced cycle showed a similar increase in spontaneous activity and response to posterior pituitary injection after the injection of 20 mg of progesterone. Two cases of anovulatory cycles showed spontaneous activity and response to posterior pituitary injection characteristic of the follicle phase. The authors conclude that the uterus of the sexually mature woman is spontaneously active and responds to posterior pituitary injection throughout the entire cycle. Its spontaneous activity and sensitivity to posterior pituitary injection are greatest in the luteal phase, both reach their maximum just before the onset of menstruation or during its first day. The weight of experimental evidence and of experience is against the claims made for the use of progesterone in treating dysmenorrhea and afterpains. If it is of value in the therapy of abortion it must be because of its action in maintaining the decidua and so making possible the vital maternal-fetal connections.

Dermatitis Venenata Caused by Manzanillo Tree—

Satulsky and Wirts direct attention to the hazards of contact with the manzanillo tree, which is found on beaches in the republic of Panama and the Canal Zone. It caused dermatitis in soldiers who were establishing a beach defense. The first patient had been awakened by severe burning and pain of his face and shortly after opening his eyes he noted that they too began to burn. There were numerous erythematous macules on the face and neck. The conjunctivas were red and edematous. The edema became so severe that on the left side part of the palpebral conjunctiva overhung the lower lid. Morphine sulfate $\frac{1}{4}$ grain (16 mg) was given subcutaneously, warm saline compresses were applied to the face and neck and an ointment containing boric acid in 5 per cent concentration was applied before evacuating the patient to a hospital. During the next four hours 60 men had to be evacuated because they were unfit for combat duty. At least 50 per cent were temporarily blinded because of severe conjunctivitis and edema of the eyelids. Daylight revealed numerous manzanillo trees in the areas where the men had slept. All the patients recovered without sequelae, and most of them were returned to duty in seven to eight days.

Chlorophyll for Ulcers—Chlorophyll in the form of an ointment or of an aqueous solution was used by Gahan and his collaborators in the treatment of 25 patients with ulcers of various origins. The ointment consisted of oil soluble derivatives of chlorophyll mixed with hydrous wool fat in the proportion of 1 to 28. The aqueous solution was made by

dissolving 2 Gm of a water soluble derivative of chlorophyll in a liter of distilled isotonic solution of sodium chloride. The ointment was used topically, the solution was used for wet dressings for ulcers which were surrounded by severe inflammatory zones. Among the 25 patients there were 19 who responded favorably to local treatment with chlorophyll. It appeared to have a stimulating effect on the supportive tissues. In some cases the production of granulation tissue in a torpid ulcer was rapid.

Prognosis and End Results in Treatment of Cancer of

Stomach—Walters and his co-workers report that from 1907 to 1938 inclusive the diagnosis of carcinoma of the stomach was made at the Mayo Clinic in 10,890 cases. The lesions in 4,648 (42.7 per cent) were considered to be inoperable, and only palliative medical treatment was given. The remaining 6,242 (57.3 per cent) patients underwent exploratory operation in the hope that gastric resection might be accomplished. Among this group, inoperable lesions were found in 2,431 cases (22.3 per cent of the entire series of 10,890 cases). In an additional group of 1,039 cases (9.5 per cent of the original series of 10,890 cases) the lesion could not be removed but some palliative procedure was performed. In 2,772 (25.5 per cent) of the 10,890 cases in which the diagnosis was established, gastric resection was accomplished. Thus approximately 1 of 4 persons had the lesions removed surgically and thereby, provided they survived the operation, had some chance of cure. The resectability rate (calculated on all patients) was 25.5 per cent. When the resectability rate is calculated from only the number of patients on whom operation was performed, it is found to be 44.4 per cent. The resectability rate is important because, even though the surgical rate may be high or may gradually increase as time goes on, this change does not mean that the ultimate results are being improved unless the resectability rate continues to be high. The mortality rate for all types of gastric resection was 16.2 per cent. With improvement in operative technic this mortality rate was reduced to 10.9 per cent for the years 1940 and 1941 together. Of the patients who underwent resection and who survived the operation, 28.9 per cent lived five years or longer and 6.3 per cent lived twenty-five years or longer. The lower the grade of malignancy according to Broders, the better was the prognosis and, conversely, the higher the grade of malignancy the worse the prognosis. Eighty-six and two tenths per cent of the patients who had carcinoma of grade 1 were alive five years after resection, whereas only 23.3 per cent of patients with carcinoma grade 4 were living after a comparable period. From the prognostic standpoint the presence or absence of involvement of the regional lymph nodes was of the greatest significance. In cases in which the regional lymph nodes were not involved the five year survival rate was 43.1 per cent, as contrasted with only 16.5 per cent in cases in which the regional lymph nodes were involved. If a patient lived five or more

years after resection of a carcinoma of the stomach the chance of survival during the ensuing years was found to be about the same as it is for any person of comparable age in the general population

Action of Tyrothricin on Fecal Streptococci.—According to Rodaniche and Palmer *Streptococcus fecalis* has been shown to possess strong resistance against sulfonamide compounds and penicillin. It seemed of interest, therefore to test its resistance in vitro and in vivo against tyrothricin. Thirty strains of fecal streptococci including only types showing alpha or gamma hemolysis were tested together with five strains of throat streptococci. The latter were included for purposes of comparison. A similar technique to that employed by Rammelkamp for the study of the action of tyrothricin on *Staphylococcus aureus* was adopted. The in vivo tests were made on albino mice. The authors found that tyrothricin is highly bactericidal and bacteriostatic to *Streptococcus fecalis* and related fecal streptococci in vitro. Considerable variation in susceptibility occurs from strain to strain. Oral administration of tyrothricin may produce inhibition of the growth of streptococci in the intestine of mice. This inhibition is most readily demonstrated when succinylsulfathiazole is administered together with tyrothricin.

Flavacin, an Antibacterial Substance Produced by *Aspergillus Flavus*.—While studying the production of penicillin, Bush and Goth isolated a mold belonging to the *Aspergillus flavus* group which produced a powerful antibacterial substance. This mold appeared as a contaminant on one of their cultures of *Penicillium notatum*. It was able to dissolve *Staphylococcus aureus* and *Staphylococcus albus*. On further study the authors found that the *aspergillus* released in the culture medium an inhibitory substance which was active against a large number of bacterial species. They have succeeded in partially purifying this substance to such an extent that its activity per milligram is comparable to that of therapeutic penicillin against gram positive cocci. Flavacin like penicillin is a water soluble and ether soluble organic acid which has a powerful antibacterial activity. It differs from gramicidin, tyrocidin and penicillin B which are protein or polypeptide in nature. Flavacin resembles penicillin in another respect it is unstable in an acid environment particularly on shaking with air. Although both penicillin and flavacin inhibit especially gram positive cocci, flavacin is more active against *Corynebacterium diphtheriae*, *Bacillus anthracis*, *Staphylococcus albus* and *Brucella abortus* than is penicillin. The available evidence suggests that flavacin is a powerful antibacterial agent against a wide variety of bacterial species.

Effects on Nutrition and Hemopoiesis of Total Gastrectomy—Of twenty-nine total gastrectomies performed at the University of Michigan Hospital, 24 patients survived the operation. The mortality rate following total gastrectomy is not prohibitive. The stomach does not play an essential role

in the digestion of fats and protein. There is no experimental evidence that removal of the stomach will produce pernicious anemia. Primary anemia is rarely encountered following various gastric operations. Gastrectomy interferes with the metabolism of iron. The absorption of dextrose is more rapid than normal. This results in a transient hyperglycemia phase that is followed by hypoglycemia. The latter phase may produce characteristic symptoms. A high protein, low carbohydrate diet is efficacious in preventing these abnormalities. A woman aged 40 is living and well four years and seven months after a total gastrectomy. Intestinal motility is decreased rather than increased. This may be due to intra-abdominal section of the vagus nerves.

Sulfathiazole in Peritonitis—Poth and Fernandez produced peritonitis in 60 animals by sectioning the duodenum 2 cm distal to the main pancreatic duct and the jejunum distal to the Treitz ligament at a point permitting an end to end anastomosis to reestablish continuity of the gastrointestinal tract. The isolated loop was washed with 10 cc of isotonic solution of sodium chloride and the washings were studied bacteriologically. The loop was dropped into the peritoneal cavity with its distal end open. Water was always available to the animals, but food was withheld for four days. Ten animals subjected to this operation served as controls. The average length of survival was two days. The remaining 50 animals were divided in five groups of 10 to determine the differential advantage of administering sulfathiazole by different routes. The survival of the animals in the different groups demonstrated the importance and therapeutic value of maintaining a high local concentration of sulfathiazole in the area of infection. The value of sulfathiazole when applied locally to the peritoneal cavity is assessed as compared to its usefulness when administered so as to maintain a relatively high general tissue concentration. A suspension of sulfathiazole may be more suitable than the dry powder for intraperitoneal administration, and repeated intraperitoneal injections may be advisable in generalized peritonitis. The results of this study indicate that the intraperitoneal administration of sulfathiazole should be fortified by maintaining a high systemic concentration of the drug by other therapeutic routes when necessary. The combined use of succinylsulfathiazole as an adjuvant to surgery of the large bowel is advocated.

Acute Abdominal Symptoms from Bite of Black Widow Spider—The pain produced by the bite is often described as resembling the pain from a pin prick or a small splinter. Frequently patients may pay little or no attention to the bite and may not give the incident in reciting the history of their illness unless specifically questioned. Usually in from one-half to two hours the patient complains of cramping pain which have their origin in the muscle groups near the location of the bite. When the bite is on a lower extremity or the genitalia the cramps are first noted in the thighs and hips. In a short time the pain is apt to spread to the abdomen and to be excruciating, comparable in severity to that caused by renal colic, perforated ulcer or coronary occlusion. Examination of the abdomen reveals a boardlike rigidity, although the abdomen usually moves with respiration. There is less tenderness than one would expect to be present in peritonitis producing such extreme rigidity. The temperature is apt to be normal when the patient is first seen, but fever is likely to develop a few hours later. The great majority of patients recover completely in from one to three days. Specific antiserum given early after the bite seems to be the most rational therapy. The author reviews 56 cases which were seen in the John Gaston Hospital, Memphis, Tenn., between 1933 and 1942 inclusive. Severe abdominal pain was the most important symptom and boardlike rigidity of the abdominal wall was usually present. There was no fatality.

Estrone in Involutional Melancholia—Gibson reports observations on 20 patients treated with estrone (theelin). The effect could be regarded as an important factor in the recovery of 5 patients, all of whom showed evidence of ovarian dysfunction. Signs of endocrine upset were present in 4 and fewer additional factors were ascertainable in this group than in the others. Estrone appeared to have a specific quality. There were 8 patients in whom it seemed to accelerate a convalescence already in evidence, and it produced a sense of increased confidence. The improvement could not be compared with that seen in the first group. At the time of treatment the physical concomitants of the menopause had passed off in 5 of the 8 and were in process of subsiding in 2. Additional factors were more pronounced in this second group and included adverse childhood conditions in 3 patients and abnormal heredity in 6. Four patients were not improved even though they were given much larger doses than the patients who recovered. Endocrine factors were prominent but adverse factors other than those of an endocrine nature reached their maximum in this group and it appeared possible that the lack of response to estrogen was due to the malignancy of these factors. Conversely those patients who responded well belonged to the group in which the minimal number of such factors could be ascertained. Three patients were worse after treatment and here an endocrine mechanism appeared implicated. Polyglandular insufficiency was present and it seemed that estrogen by upsetting still further the endocrine balance brought about the deterioration. The administration of thyroid led to recovery in one and improvement in another while adrenal cortex extract produced transient improvement in the third. This study further illustrates the complex causation of involutional melancholia. Where an element of endocrine dysfunction was present the glandular disturbance seemed of importance in the development of the psychosis. Other factors were also present. Through-

out the personality of these patients there kept recurring a tendency to be easily worried, sensitiveness pronounced conscientiousness, lack of sociability and timidity so that these seemed characteristic of the usual pre-psychotic personality. Heredity and environment played a part.

Prognosis of Peptic Ulcer in Air Force—Peptic ulcer is a bar to service in the armed forces. In all three British services most men with proved ulceration have been invalided. The proportion returning to duty is probably largest in the Royal Air Force, mainly because the proportion of skilled technicians is high and every attempt is made to keep valuable men. The medical records of over 1300 persons whose illness was diagnosed as peptic ulceration and reported during the first eighteen months of the war have been examined. Many of these were invalided but a number were retained. The rate as regards service in the Royal Air Force of the 194 with peptic ulceration who were allowed to return to duty has been followed for about two years. After this time just two thirds of the group were still serving and about a third had been invalided. About half of the patients who were fliers returned to flying duties. With regard to this group selected as being worthy of retention in the service the subsequent history suggests that help in disposal may be obtained from the rank for the higher the rank the more likely will the patient be able to carry on. Neither the length of history nor any of the various criteria of diagnosis appears to offer any guidance as to whether or not an airman after treatment for peptic ulceration is likely to withstand service life.

Meningococcal Adrenal Syndromes and Lesions H. S. Banks and I. E. McCartney —p. 771
Treatment of Osteoclastoma I. F. Brailford —p. 770

Meningococcal Adrenal Syndromes and Lesions—Banks and McCartney submit evidence that the meningococcal adrenal syndrome is a composite entity. It can be differentiated into a pure adrenal syndrome in which the main organic lesion is confined to the adrenal glands and a mixed or encephalitic adrenal syndrome in which significant lesions are present in both the brain and the adrenal glands. The pure adrenal syndrome does not seem to be invariably fatal. With modern treatment a recovery adrenal syndrome is being developed which is specific only in its evolution, happy termination and absence of direct pathologic proof. Evidence is also submitted as to various adrenal lesions which may be present in meningococcal disease. They do not all consist of pure adrenal hemorrhage. Thrombotic necrosis affecting the greater part of the gland is not uncommon. One case is described in which the main lesion appears to be a gross edema of the gland accompanied by focal areas of inflammatory adrenitis and in another case composite lesions are described including hemorrhagic thrombosis, edema and focal adrenitis. There seems to be no justification for the term Waterhouse-Friderichsen syndrome. Eleven cases of meningococcal adrenal disease are described 8 of which were fatal. Meningococci were isolated from 6 of the patients who died and from 2 of those who recovered. In 4 of those who died no significant organic lesion other than meningitis was found in the brain or the cord, but in the remaining 4 there was evidence of diffuse or focal encephalomyelitis (capillary thrombosis, hemorrhages and peri-

vascular cuffing) or of very gross edema. The former group and also the 3 patients who recovered showed relatively clear consciousness and normal rapid noiseless or acidotic breathing, while those with a cerebral lesion were deeply comatose and had rapid stertorous breathing. Prompt diagnosis and immediate treatment of the infection with sulfonamide compounds, with vigorous replacement therapy for the adrenal crisis, may lead to recovery at least from the pure adrenal syndrome.

Lymphatic Reaction in Epidemic Hepatitis—Landolt differentiates Weil's disease, the icterogenic spirochetosis, from a more benign form of jaundice. Hepatitis epidemica is the term that has been applied to the latter. The author describes the symptomatology of this condition on the basis of 12 clinical cases. The sedimentation speed of the erythrocytes is moderately accelerated and this acceleration often persists into the convalescence. The red blood picture shows no essential changes. The white blood picture presents a leukopenia or normal leukocyte values. The differential count discloses a typical lymphatic reaction with a predominantly plasmacellular metamorphosis. Differentiation of hepatitis epidemica from icterus simplex is extremely difficult. The latter condition cannot be regarded as an etiologic unit and some cases of icterus simplex may be sporadic cases of hepatitis epidemica. The lymphatic reaction observed in hepatitis epidemica suggests a relationship to infectious mononucleosis, particularly because the latter condition is often associated with a hepatic swelling and the presence of urobilin and urobilinogen in the urine. Swelling of the spleen is also observed in both diseases. Although these disorders have several points in common, their identity is not likely.

 *Prophylaxis of Measles. F. Bazán and E. Sujoy—p. 825

Hyperglycemic Dyspituitarism—D'Angelo Rodriguez and Puebla describe a syndrome of hyperglycemia observed in patients with diabetes. It is caused by dysfunction of the pituitary gland due to diminution or absence of gonadal hormones. The symptoms of the syndrome are dizziness, headache, rapid increase in weight, eczema, pruritus, loss of appetite, meteorism, diminished libido, menstrual disorders, nervousness, hepatomegaly, increased cholesteremia, moderate arterial hypertension and enlargement of the dextrose tolerance curve. The therapy consists of estrogens and androgens alone or alternating. Six cases of the syndrome are reported. The patients have been observed for more than two years after discontinuation of successful hormone therapy.

Prophylaxis of Measles—Bazán and Sujoy studied two groups of 37 children who had been given intramuscular injections of either placental extract or blood serum from patients convalescent after measles and who then were exposed to the contagion. The age of the children varied from 6 months to 10 years. The dose of the extract varied from 2 to 8 cc, the dose of blood serum from 3 to 10 cc. The authors found that placental extract and convalescent serum when administered in proper dose produce passive immunity in 81 and 90 per cent respectively of the treated children. The percentage of immunity increases to 90 and 95 respectively if cases of primary measles are disregarded.

 Hypoglycemia After Depot Insulin. C. Brentano—p. 275

Hypoglycemia in General Practice—According to Umber, hypoglycemia is characterized by neurosympathetic symptoms such as tremor, weakness, accelerated pulse, palpitation, sweating and hunger and by cerebral psychotic symptoms. The latter as a rule do not appear as suddenly as those of the first group. They develop more gradually and may be preceded by headache, depression and visual disturbances. There may develop aphasia, confusion, temporary unconsciousness, stupor, jactitation, temporary psychosis, compulsive laughing or crying and prolonged loss of consciousness. There may also be pupillary rigidity and a positive Babinski sign. Hypoglycemic attacks often begin with impudent, mischievous and obstinate behavior in otherwise well behaving children. The character of the psychotic reactions in hypoglycemia may be determined by individual psychotic predisposition. Treatment with protamine zinc insulin is more likely to provoke the insidious cerebral symptoms than the sudden neurosympathetic symptoms. Such latent hypoglycemia is not desirable, and great care is necessary in estimating the proper dose of depot insulin. There is a spontaneous hypoglycemia in which insulin medication plays no part. This he further differentiates into that caused by direct insulinism and that caused by indirect insulinism. Hypoglycemia developing in the presence of insulinomas or of simple functional hyperplasia of the islands of Langerhans belongs to the first group, whereas that in which hypophysial functions are involved belongs to the second group. In the treatment of hypoglycemia dextrose or levulose is effective. Suitable diet will prevent the attacks. Calcium and atropine derivatives will counteract the sympathetic irritability. In cases in which insular tumors are the cause of the hypoglycemia, surgical treatment may obtain a cure. The patient's constitution, his endocrine and central nervous makeup, is of great importance in the development of hypoglycemia.

Rheumatism in Tropical and Subtropical Countries—Büngeler points out that variable climatic conditions may prevail in the same latitude as the result of differences in altitude and other factors. This is exemplified by the different climatic regions in the state of São Paulo, which is partly tropical and partly subtropical. Büngeler based his study of the incidence of rheumatic disease in São Paulo on more than 600 postmortem examinations. He recognized as cases of rheumatic disease only those which showed in the heart or the joints or in both the characteristic Aschoff-Geipel nodes, typical nodule-like scars or signs of rheumatic endocarditis or its sequels. Signs of rheumatic disease were present in 54. The incidence of rheumatism is not dependent on climatic factors. Büngeler thinks that rheumatism is just as frequent in the tropics as elsewhere. Rheumatism everywhere is a problem of focal infection. The high incidence of rheumatism in tropical Brazil suggests that the tropical climate has no therapeutic effect on the disease. Elimination of foci of infection is of primary importance in treatment of rheumatism.

Book Notices

A Manual of Clinical Therapeutics. A Guide for Students and Practitioners. By Windsor C. Cutting M.D. Associate Professor of Therapeutics Stanford University School of Medicine San Francisco. Cloth Price \$4. 1p 609 Philadelphia & London W. B. Saunders Company 1943

The introductory chapter in this compendium is on general problems in therapeutics; then there are terse statements of what to do for amazingly large lists of diseases in the following classifications: the various types of infections; other diseases, probably infectious; nutritional diseases; vitamin deficiencies; endocrine diseases; metabolic diseases; diseases due to allergic states; diseases due to physical agents; diseases of the gastrointestinal tract and the peritoneum; diseases of the pancreas, liver and bile passages; the heart; the peripheral circulation; the blood and spleen; the respiratory system and mediastinum; the genitourinary system; the muscles, bones and joints; the skin; the peripheral nerves; the central nervous system and the mind. Then come appendices on special procedures, physical therapy, symptoms and treatment of poisoning, diet lists, metric and English equivalents, tables and charts for weight, height and age, abbreviations and other aids in prescribing clinical physiologic data, quantitative methods for controlling the therapeutic use of drugs, lists of prescriptions, drugs and doses, a list of works of reference and an adequate index. Nearly everything is here in fact nothing of importance seems to have been omitted save that intangible something which marks the difference between a contribution to medical literature and a mere medical book. This is just a medical book, no one, having once paged through it, would ever think of opening it again merely for the pleasure of reading or for contact with the mind and experience of its author. But the book is filled with dogmatically phrased statements of what to do for what your patient "has" and they may be quickly got at. It will probably enjoy a large sale.

Elements of Food Biochemistry. By William H. Peterson Ph.D. Professor of Biochemistry University of Wisconsin Madison. John T. Skinner Ph.D. Assistant Chemist Kentucky Agricultural Experiment Station Lexington and Frank M. Strong Ph.D. Associate Professor of Biochemistry University of Wisconsin Madison. Cloth Price \$3. 1p 291 with 34 illustrations. New York: Prentice Hall Inc. 1943.

The authors state that the purpose of this book is to emphasize the chemistry of the constituents of food and the chemical changes that these constituents undergo in the process of metabolism. Written to serve primarily as a textbook in food biochemistry for college undergraduates, the book will no doubt prove useful to many other persons as well. The presentation of the various topics of interest is about as elementary as is possible when one considers the numerous chemical formulas necessarily involved in the discussion of any phase of biochemistry. The nine chapters cover carbohydrates, fermentation, food products, acidity, lipides, proteins, mineral elements in nutrition, water, vitamins and enzymes. Attempts are made to show the relation of many of the topics to industry and economic life in general. For example in the chapter on carbohydrates one finds a table setting forth the economic importance of some industries based on carbohydrates elsewhere other tables deal in similar fashion with fats and proteins. Thirty-four illustrations aid in arousing interest. Important substances like vitamins and pepsin that have been isolated in pure form are discussed and photographs of their crystals presented. Other photographs illustrate some of the vitamin and mineral deficiencies. In the appendix will be found several tables of interest. One gives the proximate composition of many foods, whereas another deals with the occurrence of mineral elements in representative foods, a third with trace elements and a fourth with vitamin content. The usefulness of the volume is further enhanced by an index. For the reader who has had only an introductory course in organic chemistry, this book can undoubtedly be recommended. More advanced students however will desire a more extended and detailed treatment of the subject than is offered in this volume.

The Pharmaceutical Recipe Book (R. B. III). By Authority of the American Pharmaceutical Association. Prepared by the Committee on Recipe Book of the American Pharmaceutical Association. Third edition. Cloth Price \$5. 1p 71. Easton Pa. Mack Printing Company 1943.

As stated in the preface the Recipe Book represents the outcome of an effort of the American Pharmaceutical Association to place in the hands of the practicing pharmacist a reliable and comprehensive book of recipes applicable to his business. The book is divided into several parts relative to the various types of formulas. The edition represents a complete revision of this formulary with a view of effectiveness of the preparations included and new ones gleaned from the medical literature, hospital formularies and foreign compilations. The sections on podiatry (chiropodologic), dental and veterinary products and cosmetic preparations have been revised. Many new features have been introduced, such as a table of Latin terms and equivalents, a glossary of synonyms, a table of acceptable coal tar dyes, a vitamin synopsis, and sections devoted to diabetic and ophthalmic preparations. However, the section on photographic formulas has been deleted. The book lends little value to the physician but a hand to medical quackery. Nevertheless it is an advancement over the usual polypharmaceutic mixtures or imitation "patent medicines" heretofore exploited by the publishers of pseudoscientific magazines. The volume is to be recommended in that it does not make any claims for remedial action assuming no responsibility for the therapeutic uses. The text contains some fourteen hundred formulas.

Victories of Army Medicine. Scientific Accomplishments of the Medical Department of the United States Army. By Edgar Erskine Hume. Colonel Medical Corps United States Army. Cloth Price \$3. 1p 20 with 79 illustrations. Philadelphia Montreal & London J. B. Lippincott Company 1943.

Colonel Hume is at this writing in charge of the medical aspects of government in Sicily. His book is largely based on lectures delivered in 1942 at the College of Physicians of Philadelphia and the Johns Hopkins University, also the 1943 Beaumont Lecture before the Wayne County Medical Society in Detroit. The great scope of interest is indicated by sections on anthropology, ornithology and surgery. These considerations are followed by advances that developed with each of the great wars in our history. There are chapters on the various divisions of the Army Medical Department, lists of men who have served as librarians in the Army Medical Library, commanders in the Army Medical School, lists of general hospitals and much other valuable material. There are also great numbers of portraits of men who have contributed greatly to the work of the Army Medical Department. The volume is an excellent compilation of exceedingly useful material relative to the medical services of our armed forces. The useful information that it makes available should cause its addition to every medical library.

Chemistry and Methods of Enzymes. By James B. Sumner Professor of Biochemistry Cornell University Ithaca New York and G. Fred Somers Instructor in Biochemistry Cornell University. Cloth Price \$5. 1p 365 with illustrations. New York Academic Press Inc. 1943.

Since each of the countless chemical reactions which take place in living cells are catalyzed by enzymes, these substances may properly be considered as the most important constituents of cells. Enzymatic reactions are, moreover, generally specific in nature so that each cell must contain a great many enzymes. It is estimated, for example, that liver cells carry out over a thousand chemical reactions involving oxidation, hydrolysis and synthesis and that each of these reactions is catalyzed by a specific enzyme. Only a small fraction of these enzymes have thus far been isolated and studied but new ones are constantly being discovered and the literature on enzyme chemistry is growing rapidly. In the present book the authors present a general survey of modern enzyme chemistry without describing in detail any particular enzyme or class of enzymes. The subject matter is divided into four parts. Part 1 deals with the general properties of enzymes. Part 2 contains seven chapters dealing with such hydrolytic enzymes as esterases, carbohydrases, nucleases, amidases and proteases. Part 3 consists of nine chapters dealing with various classes of oxidative enzymes.

Part 4 contains a chapter on hydrases and mutases and a final chapter on carbohydrate metabolism in which the authors show how individual enzymes fit into the general picture of carbohydrate utilization in cells. Throughout the book important members of each class of enzymes are discussed briefly from the standpoint of history, occurrence, action, specificity, activity measurements, activation and inactivation, preparation and properties. These brief descriptions of the important properties of individual enzymes, together with the many hundreds of references to the original literature, serve to make this a very useful book for students and workers in this important field.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1942 with the Comments That Have Appeared in The Journal (Cloth Price, \$1) Pp 207 (Chicago: American Medical Association 1941)

Through the years the size of this volume has grown with the increased work of the Council on Pharmacy and Chemistry until the present edition has the same number of pages as the book published in 1908 which covered the Council's first four years of activity. This volume epitomizes that phase of the Council's work which may be said to be collateral to the 'acceptance' of drugs—the informative consideration of current medical problems in the interest of rational therapeutics. It contains reports of studies by private investigators which were originally published in *THE JOURNAL* under the sponsorship of the Council, such as preliminary discussions of new developments in therapeutics and timely articles on the status of recognized agents as well as reports of omission or rejection of products from New and Nonofficial Remedies. It also offers a record of current decisions on matters of Council policy.

Several of the reports are of particular interest for various branches of medical science: the use of bulk ether in anesthesia, the absorption of surgical gut (catgut), the higher types of antipneumococcus rabbit serum, the surgical and medical treatment of animals with experimental hypertension and the status of racemic epinephrine solutions for oral administration. The reports in this small compact volume represent expert medical consensus and are proffered to aid in the consideration of the value of therapeutic agents.

Methods for Diagnostic Bacteriology: A Complete Guide for the Isolation and Identification of Pathogenic Bacteria for Medical Bacteriology Laboratories By Isabelle G. Schaub, A.B., Instructor in Bacteriology, Department of Pathology and Bacteriology, Johns Hopkins University School of Medicine, Baltimore, and M. Kathleen Foles, A.B., Bacteriologist in Charge of the Diagnostic Bacteriological Laboratory of the Medical Clinic, Johns Hopkins Hospital, Baltimore. Second edition. Cloth Price, \$3.50. Pp 430. St. Louis: C.V. Mosby Company, 1943.

In the second edition of this laboratory guide in bacteriology there has been added a new section on laboratory procedure in outline form and methods for the quick identification of microscopic organisms based chiefly on their colony characteristics. The format of the manual is so arranged that a blank page faces each printed page, allowing for the addition of notes to meet the bacteriology worker's specific needs. In a sense there is no "routine" bacteriologic procedure, as the methods used depend more often than not on the diagnostic acumen of the worker. What this manual attempts to present is a specific detailed outline of bacteriologic laboratory methods to suit a large number of the more usual clinical cases. The methods presented are entirely modern and have the advantage of being the procedure actually used at the Johns Hopkins Hospital Laboratory. This is not an elementary textbook. It is intended as a guide for the fairly experienced worker and as such probably has considerable usefulness.

Rehabilitation of the Tuberculous By H. A. Pattison, M.D., F.A.C.P. Cloth Price \$2.50. Pp 186 with illustrations. Livingston, Columbia County, New York: Livingston Press, 1942.

The author has been for twenty-five years concerned in the field of rehabilitation of the tuberculous. Hence this book is among the most authoritative works available in the field concerned. Sanatorium treatment, vocational training, family relief, marriage, mental aspects, allergy and the human constitution are discussed. There are also, in the second part of the book, excellent descriptions of special projects such as those at Saranac Lake, Papworth Village and many another center of rehabilitation and sheltered workshops here and abroad.

Emotional Hygiene: The Art of Understanding By Camilla M. Anderson, A.B., M.D., Consulting Psychiatrist for the American Red Cross. Cartoons by Dorothy G. Stevenson. Third edition. Cloth Price \$2. Pp 253, with illustrations. Philadelphia: New York & Montreal: J.B. Lippincott Company, 1943.

This is a much improved edition of a book which has been definitely successful in aiding individuals to adjust themselves. The author is a practicing psychiatrist with an excellent background, and, as we said in the review of the first edition, 'This is one of the few books on mental hygiene sufficiently well written and widely enough applicable so that it might be given to the interested reader without medical training who requests a book on this subject. There are many chuckles and pertinent illustrations, both verbal and pictorial, and practical cases are taken up and discussed in an intelligent manner.' It deals with the need of the patient to be aware that he should grow up, that he should not run away from problems, and there is also a discussion of psychiatric nursing, as the book is one as much for the psychiatric nurse as it is for the layman who would like to read something enlightening with regard to minor problems. It is a safe book to give to readers who are interested in their own problems, provided these problems are not so serious that the reader is likely to get numerous disorders, as is so common in medical students, that is, identification of a wholesome personality with the unwholesome picture described in the volume. Certainly no book can supplant the therapist, but, in this day and age of reading on every subject, when the patient demands a book, this is one which can be given to him.

Diagnosis of Uterine Cancer by the Vaginal Smear By George A. Papinicolaou, M.D., Ph.D., Department of Anatomy, Cornell University Medical College, New York, and Herbert F. Traut, M.D., Department of Obstetrics and Gynecology, Cornell University Medical College and New York Hospital. Cloth Price, \$5. Pp 47 with 11 colored plates. New York: Commonwealth Fund, London: Oxford University Press, 1943.

This is a descriptive atlas of the cells in vaginal smears under various conditions, normal and pathologic, with special emphasis on the diagnostic value of such smears in carcinoma of the cervix and the fundus of the uterus. The preparation and staining of vaginal smears is described in detail. The procedure appears to be simple and suitable for routine use. The morphologic appearances on smears are excellently illustrated in eleven plates of drawings and photomicrographs, all in colors. "Patient and repeated search of multiple preparations by well trained microscopists is essential to success." It is pointed out by the authors that the vaginal smear cannot be depended on for the ultimate diagnosis of uterine carcinoma in the place of biopsy and microscopic sections. The evaluation of individual cells or small groups of cells is more difficult than of carcinoma in tissue sections. But recognition of carcinomatous cells in vaginal smears may lead to the diagnosis of carcinoma while it is still in the early and superficial stage. The atlas is based on the examination of specimens from some 3,000 women and will be of valuable help to all who are interested in the systematic study of vaginal smears.

Urine and Urinalysis By Louis Gershenfeld, Ph.D., Ph.M., D.Sc., Professor of Bacteriology and Hygiene and Director of the Bacteriological and Clinical Chemistry Laboratories at the Philadelphia College of Pharmacy and Science. Second edition. Cloth Price \$3.25. Pp 304 with 42 illustrations. Philadelphia: Lea & Febiger, 1943.

This publication will be welcomed by practitioners and others who are especially interested in the analysis of the urine. Much new material has been added for this edition and the book has been thoroughly revised. The author covers the subject ably and completely. First he discusses the structure and function of the kidney, the definition of urine and the collection of samples. He continues with the physical and chemical characteristics of the urine, its pathologic constituents and its qualitative, quantitative and microscopic analysis. The book is completed with a section of special urinary tests and tests of kidney function. The discussions of the practical importance of the various tests are excellent. However, the book will be found to be too detailed for the average laboratory worker who is interested usually in but one good test for any particular constituent of urine. For workers interested in this subject the book is unqualifiedly recommended.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. INQUIRIES CONCERNING COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SAFETY LENSES FOR INDUSTRIAL USE

To the Editor—In one of our plants we have a ruling that all employees must wear safety lenses. We have had some criticism from some members who state that certain local physicians and opticians have advised them that the wearing of such lenses could injure their eyes permanently. 1. Has thickness of safety glass any bearing on prescription glasses? 2. Is there any corrective effect or magnification in the clear lens glasses? 3. Will clear lens safety glasses injure the eyes of a person not now requiring correction or hasten the day when they may need correction? 4. Is there any advantage of a flat clear lens over a curved clear lens? 5. Must curved lens glasses be fitted more exactly in relation to the eye than a flat lens? 6. Could clear lens safety glasses cause blood-shot eyes or nauseate a person not requiring glasses? 7. What are the allowable limits in grinding regular prescription lenses? 8. What are the allowable limits for clear safety glasses lenses?

H. W. Garton, M.D., Fort Wayne, Ind.

ANSWER—1. For all practical purposes, no. Even clear white glass absorbs a certain proportion of visible rays of light (6 per cent or more, depending on its thickness). Objects never appear exactly the same through glass as they do without the glass. Indeed, physicians as well as lighting engineers should take this factor into consideration when advising regarding the amount of light workmen need on the job. Occasionally a person is found who is annoyed by the almost negligible difference in apparent size of objects seen through curved glasses of appreciable thickness, especially if there is a notable difference in the prescription for the two eyes. Indeed, it is on this principle that differences in size are corrected—the so-called aniseikonic lenses. The aniseikonic factor does exist, but undoubtedly it is almost negligible. Of far greater importance is the exact correction of the refractive error. If the glasses have no correction or if the correction is approximately the same for the two eyes and if the glasses are of the same curvature and thickness, the difference of appearance of objects with and without goggles is the same as the difference in viewing an object in space through a pane of glass and without the pane or glass interposed.

2. See answers to 1, 7 and 8.

3. No. On the contrary, many eyes are saved by wearing goggles. Industrial surgeons always ask workmen whose eyes are injured, "Where were your goggles?" And almost invariably there is a sheepish answer such as "I thought I wouldn't need them at the moment."

4. No. The curved clear glass will resist impact better than the flat glass. Also, because of the eyelashes the curved glass goggles can be fitted closer to the eyes and give a greater field of vision. See also answer to 1. Mr. C. A. Partenhimer of the American Optical Company says: "In very few cases we find some workmen prefer a flat lens to a curved lens, but 95 per cent of our customers are more than anxious to have us furnish the curved clear lens, due to the fact that today's production is not sufficient to permit us to supply the demand for curved clear lenses much to the dissatisfaction of our safety trade. We might state that a curved lens is an approximation of the curve of the eyeball—is capable of rendering more space for eyelashes, thus permitting the goggle to be fitted close to exclude foreign matter. It deflects flying objects much more readily than a flat lens and is capable of withstanding much more severe impact and last but not least it does not permit annoying reflections that are often present when flat lenses are mounted in safety goggle frames."

5. Care should be taken to fit all goggles so that they are comfortable, are held in the proper position before the eyes and give clear vision for the job. If the worker has eyes which see objects of different size or if he has pronounced inequality in the strength or the prescription for the two eyes, special care should be given to filling the order for curved glass goggles.

6. Probably not. Many people depend on the air to dry the normal tear supply. Such may find that any glasses and espe-

cially goggles interfere with nature somewhat. Many people perspire easily and the sweat often collects in the goggle cup and may be slightly irritating at first. After a few days, however, nature usually adapts itself if the goggles are well fitted and well ventilated. Otherwise the workman may be compelled to take them off occasionally to wipe his brow and his eyes and to clean the goggles. If he wipes his eyes with a dirty handkerchief he is apt to get red eyes. The nuisance is immaterial as compared to the loss of an eye. Nausea may develop in a workman for any one of many reasons—the boss, the foreman, the working hours, the job, his fellow workmen and the like.

7 and 8. In the 1938 edition of the National Bureau of Standards Handbook H 24 "American Standard Safety Code for the Protection of Heads, Eyes and Respiratory Organs," issued by the U. S. Department of Commerce, National Bureau of Standards page 6 paragraph 16 appears the following:

General Requirements for Glass

(a) All Glass—Glass for lenses and windows of protectors shall be hard, substantially free from striae, air bubbles, waves and other flaws. Except when the lens is ground to provide proper optical correction for defective vision, the front and rear surfaces of lens and windows shall be smooth and parallel within the following limits:

Windows and end cover glasses for same, 35 minutes of arc ($\frac{1}{2}$ prism diopter).

Lenses and cover glasses for lenses 9 minutes of arc ($\frac{1}{3}$ prism diopter).

"The glass shall not be negative in refractive power in any meridian, shall not have a positive refractive power in any meridian greater than 0.12 diopter, and shall not have a greater difference in refractive power between any two meridians than 0.06 diopter."

(b) Goggle Lenses—All lenses shall have dimensions not less than $1\frac{1}{2}$ inches (38 mm) in the vertical direction and $1\frac{3}{4}$ inches (44.5 mm) in one horizontal direction. It is recommended that circular lenses not involving optical correction be of a uniform diameter of $1\frac{9}{100}$ inches (50 mm).

As a matter of fact, during wartime we often have to be content with prescription lenses within $\frac{1}{3}$ diopter (0.12 diopter) and a few degrees off axis if the prescription calls for a cylinder under 1 diopter.

UNUSUAL TYPE OF PARALYSIS OF FACIAL NERVE

To the Editor—A locomotive engineer aged 54 became suddenly ill with a paralysis of the right side of his face. When I saw the patient three days later I made a diagnosis of Bell's palsy of rheumatic origin due to exposure to drafts on the locomotive. There was obliteration of the nasolabial fold, inability to whistle to raise the right eyebrow and to wrinkle the right forehead and the mouth drooped but the right eye could be closed. No disturbance of taste was present. There was periauricular pain and tinnitus of the right ear. Except for a blood pressure of 160/90 and large tender lymph nodes (the right larger than the left) at the angle of the lower jaw and swelling of the right side of the face (especially around the eye) the physical examination was negative. The following day the systolic blood pressure dropped to 136 and has since remained normal. Application of moist heat has reduced the swelling of the face. The lymph nodes have decreased in size and are much softer. The temperature has remained normal. Is this a case of Bell's palsy (all textbooks stress the fact that inability to close the eye—Bell's phenomenon—is invariably present)? Will tonsillectomy have a beneficial effect on this condition and if so how soon could it be done? What other measures are indicated? Is there any substitute for faradization which is not available in a town of the size of this? Any suggestion will be appreciated.

Mauro Rosenberg, M.D., Auburn, N. Y.

ANSWER—The onset of the weakness of the right side of the face was indeed similar to that found in Bell's palsy, ordinarily due to exposure. There are however various types of paralysis of the facial nerve and a considerable number of variants have been observed particularly in the last few years. These variants have been in all probability due to neurotropic virus infection and are not of the same type ordinarily associated with the clinical syndrome known as Bell's palsy. In the type described by Bell it is indeed true that the inability to close the eye on the affected side is almost inevitably present although it cannot be said that this is a fixed rule. Because the eye could be closed does not preclude a diagnosis of paralysis of the facial nerve of some type. When there is associated with this tenderness of the lymph nodes at the angle of the lower jaw and a swelling of the right side of the face the symptoms are suggestive of more than an ordinary Bell's palsy.

Tonsillectomy during the acute stage of the disease should not be advised. In a patient of 54 moreover care should be exercised with regard to ascertaining the degree of infection in the tonsils before they are taken out.

There are no other measures indicated except the ordinary care of a facial paralysis. As long as the right eye can be closed there is little danger of ulceration of the cornea. This is fortunate as it avoids one of the more serious complications of Bell's palsy. If the paralysis is severe and lasts more than a week or two it is unlikely that the muscles supplied by the facial nerve on the right side would respond to faradism, and galvanism would be the only kind of electricity capable of moving the muscles. If the condition does not clear up after two or three weeks and the faradic response has not returned, galvanic treatment of the muscles is advised, as it allows the muscles to move and thus helps to keep them in their normal physiologic state. It has no effect on the regeneration of the nerve. If the proper galvanic battery is not available, usually one can be rented from a suitable source in a large city.

SURGERY OF PERIPHERAL BRANCHES OF TRIGEMINAL NERVE

To the Editor—I have observed a number of cases of chronic antrum infection with extensive bone destruction involving the roof of the antrum in which the infraorbital nerve was embedded in dense granulation tissue and had to be removed, in other cases the infraorbital nerve was removed to treat infraorbital neuralgia. In some of the cases the upper teeth were missing before operation. What is known about the harmful effects on the teeth and other structures after removing this nerve? I found only a few unsatisfactory references in the literature. Is anything known about trophic changes in the skin of the cheek following the isolated removal of this nerve? In some cases of infraorbital pain long after previous Caldwell-Luc operations, revision of the antrum showed the infraorbital nerve fibers to be surrounded by dense scar tissue (microscopic examination). In one of the cases we removed part of the infraorbital nerve and left a stump of it exposed, after which the pain in the infraorbital region reappeared. We found at a latter operation that this stump again was embedded in thick scar tissue and only after removing the entire length of the nerve beyond the posterior antral wall did the pain disappear entirely. In this particular case there was a very annoying burning painful sensation in the region of the nasolabial fold and upper lip. Is such a case similar to what is otherwise known as causalgia?

M D, New York

ANSWER—Various branches of the trigeminal nerve, including the maxillary, have been repeatedly sectioned without causing any "trophic" change in or harmful effects on the skin or the teeth. Destruction of these peripheral branches of the trigeminal nerve was once commonly practiced for the relief of trigeminal neuralgia. The relief so obtained is always temporary, because the amputation neuroma which forms on the end of the nerve and the scar tissue about it soon again supply the peripheral stimuli usually requisite for the development of the painful paroxysms of this disease. It is accordingly not surprising that in the instance cited in the query similar scar tissue irritated this sensory nerve, causing pain which was referred to the peripheral distribution of the involved nerve. The situation was comparable to that seen with amputation neuromas in the extremities. It is not similar to causalgia, which develops with partial lesions of the peripheral nerves, principally the median in the upper extremities. Causalgia is characterized by a most disagreeable burning pain which is commonly associated with emotional reactions on the part of the patient. In addition there are changes in the skin, which becomes cyanotic, light and glossy. The nails curve and grow irregularly. The skin is commonly very sensitive to touch and to drying. The joints become stiff.

BIFOCALS FOR YOUNG PEOPLE

To the Editor—A local optometrist prescribes bifocal lenses for a large number of young people and children, some of whom are as young as 7 years. The ones who have come to me for subsequent examination show no disturbance of muscle function and no weakness of accommodation. I cannot help but think that this is a harmful procedure yet can find nothing in the literature regarding it. Kindly advise if I am correct in this assumption and also what the immediate and remote effects of this would be on the eye.

M D, Iowa

ANSWER—It is certainly not considered good practice to prescribe bifocals for young people except in the presence of a convergent squint which becomes greater when the eyes are used for near vision. Other than this there is no indication for the procedure except in paralysis of accommodation. The use of bifocals by such young persons would possibly have a tendency to relax accommodation to an extent which would favor the early onset of presbyopia. The physiologic relationship between convergence and accommodation would also be prevented or interfered with and a divergent squint might possibly develop in some of these cases as a later result. One would certainly feel like condemning the procedure entirely except under the conditions previously mentioned.

ANESTHESIA FOR TONSILLECTOMY AND RESUSCITATION IN CHILDREN

To the Editor—Please advise what the safest and best general anesthetic is for tonsillectomies in children, what precautions to take to prevent sudden respiratory failure in children under ether and the best methods of resuscitation.

M D, Illinois

ANSWER—The safest and best method of general anesthesia for performance of tonsillectomy on children is to give ether by insufflation. Anesthesia may be induced with nitrous oxide, oxygen and ether, it can be maintained by drop ether for a short time, followed by insufflation with ether vapor delivered through a hollow metal hook placed in the corner of the mouth or through a tube connected with a mouth gag.

Precautions that tend to prevent sudden respiratory failure are to avoid too deep a plane of anesthesia, to have the patient's head a little lower than his hips, to keep the throat cleared or blood by using suction, to avoid obstruction of the airway with sponges, to depress the tongue in such a way as not to obstruct respiration, to use pressure in the tonsillar fossae, to control hemorrhage or to tie off bleeding vessels definitely and then, as soon as the operation is over, to discontinue administration of the anesthetic agent and to turn the patient to the prone position so that blood and mucus will drain from the mouth and not accumulate in the throat.

The best method for resuscitation is to insert an intratracheal tube and inflate the lungs with oxygen or air. If a tube is not available, the oxygen will have to be administered, probably under some pressure, usually by pressing the bag on the gas machine by hand. However, when a tube is not available, accumulation of blood in the throat creates a hazard, as blood may be forced into the trachea while forcing oxygen into the lungs. Thus this danger also obtains when an alternate method of artificial respiration is used, wherein one person presses on the patient's chest and then while he releases his pressure another person presses on the bag of the gas machine to force oxygen back into the chest. This is continued rhythmically and the patient can be kept in moderate Trendelenburg position during the resuscitation. Respiratory stimulant drugs may be used, but it is most important to give artificial pulmonary ventilation immediately.

VITAMIN K TO PREVENT HEMORRHAGIC DISEASE OF NEWBORN

To the Editor—A patient has a baby due early in June 1943. Her last child was born in July 1941 and lived only ten hours. She was under the care of a doctor who is now in military service, but the death certificate and the mother state that the baby died from hemorrhagic disease of the newborn. The patient says the doctor told her that "the blood would not clot." The woman is a sextipara. Her periods are irregular, she sometimes skips one or two or even three periods. That is the reason I cannot fix the date of her confinement accurately. I should like to know the best way to use vitamin K (and the best form) in order to prevent hemorrhagic disease in this coming baby.

Persis Straight Robbins, M D, Bradford, Pa

ANSWER—It has been recommended by competent investigators that, for prophylaxis, vitamin K in such instances as mentioned in the communication be administered as follows. The mother should be given a daily dose of 1 to 2 mg of menadione or a similarly potent vitamin K substance in capsules or tablets beginning not more than one month before the estimated date of confinement and continuing up to delivery. If the mother is not seen until labor has begun, she should be given an immediate intravenous injection of 4 mg of a water soluble preparation. Elevation of the infant's prothrombin level occurs quickly after parenteral injection of a water soluble vitamin K substance in the mother. If more than fifteen hours elapse between the injection of the drug and delivery, it should be repeated. As an added precaution the infant should be given 1 mg of vitamin K substance intramuscularly soon after delivery. It may be advisable to repeat this dosage twelve hours later to afford added protection.

PROPHYLAXIS OF POLIOMYELITIS

To the Editor—We are having a slight epidemic of poliomyelitis. Is there anything of value to use prophylactically?

R. L. Johnson, M D, Pittsburg, Texas

ANSWER—At the present time there is no agent that can be used successfully for prophylactic use against poliomyelitis. Several agents have been tried in the past, namely picric acid and aluminum sulfate as nasal sprays, without any significant value in the prevention of the disease. Such measures as avoidance of crowds and needless contact exposures, good environmental sanitation measures with proper disposal of excreta, control, pure milk, water and food supplies and good personal hygiene are still the only available procedures.

CAUSES OF REJECTION AND THE INCIDENCE OF DEFECTS

AMONG 18 AND 19 YEAR OLD SELECTIVE
SERVICE REGISTRANTS

COLONEL LEONARD G ROWNTREE
MEDICAL RESERVE CORPS, UNITED STATES ARMY

KENNETH H MCGILL

AND

THOMAS I EDWARDS, PH D

WASHINGTON, D C

Data on rates of rejection, causes of rejection and the incidence of physical and mental defects among 18 and 19 year old registrants are being presented here in response to numerous requests for information on the physical status of this age group. The information has been taken from a sample of 45,585 reports of physical examination and induction, D S S Form 221, received at National Headquarters of the Selective Service System. They represent physical examinations of 42,273 white and 3,312 Negro registrants made at local boards and induction stations during December 1942 and January and February 1943.¹

Registrants born on or after Jan 1, 1922 and on or before June 30, 1924 were required to register at Selective Service local boards on June 30 1942 in the fifth registration but they did not become liable for training and service until the Selective Training and Service Act of 1940 was amended effective Nov 14 1942. Several factors limit the population under discussion here. Large numbers of physically fit 18 and 19 year old youths entered the armed forces by direct enlistment up to Dec 12, 1942, when induction by enlistment was discontinued. The Selective Service System was notified when registrants enlisted in the armed forces but was not advised of the physical findings of either accepted or rejected volunteers. During the period represented by these data many youths remained in school or college under programs supported by the Army and the Navy which permitted them to finish a course of study before being called up for examination. Young men who had entered war industries or who were needed on farms and had been deferred because of occupation were not examined physically. The remaining 18 and 19 year olds whose order numbers were reached during December 1942 and January and February 1943 were called up for physical examination unless grounds for deferment existed and it is

this group of 18 and 19 year old registrants whose records are available for sampling and for study.

At local board physical examination the physician was instructed to note whether or not certain manifestly disqualifying defects were present. At this time a blood sample was drawn for serologic test for syphilis. If one or more of the defects listed on D S S Form 220 List of Defects was present the registrant was rejected by the local board, if none of the listed defects were present the registrant was forwarded to an induction station, where Army physicians and civilian specialists gave him a complete physical examination. Each defect noted was recorded and the important ones were listed at the foot of the physical examination form in the space labeled "Summary of defects in order of significance." Each defect listed in this space was coded and tabulated in the last three columns of figures in table 2. If the registrant was rejected at the induction station the cause or causes of rejection was stated. If two or more defects were present the one listed first was used as the cause of rejection unless this was clearly misleading, and such defects and causes of rejection at local boards have been tabulated in the first three columns of figures in table 2.

In this paper, registrants have been counted as rejected if they were not accepted for general military service. However, a substantial number of registrants who were not acceptable for general military service were inducted for limited service. If these men accepted for limited service only had been counted as inducted for the purposes of this paper the rejection rates would have been lower, particularly for rejections due to defective vision and musculoskeletal defects.

REJECTION RATES

Table 1 shows the local board and induction station rejection rates for white and for Negro registrants born in 1923 and 1924. Of the white youths called up for physical examination, 23.8 per cent were rejected either at local boards or at induction stations. The corresponding rejection rate for Negro youths was almost twice as high, 45.5 per cent.

The rejection rates for 18 and 19 year old registrants are only slightly lower than the rejection rates for older registrants, but caution should be exercised in drawing conclusions from this since as noted previously a large proportion of physically fit youths were not liable for examination either (a) because of previous enlistment in the armed forces (b) because of programs that postponed examination and induction until a course of training has been completed or (c) because of employment in war industry or agriculture.

¹ From the Medical Division and the Division of Research and Statistics, National Headquarters, Selective Service System.
² A previous article (Rowntree, L. G., McGill, K. H., and Folk, O. H., Health of Selective Service Registrants, J. A. M. A. 115: 1223-1227 [April 4] 1942) summarized data on 19,623 Reports of Physical Examination, D S S Form 200 for registrants and volunteers 18 to 44 years of age made during the period November 1940 through May 1941.

² Standards of Physical Examination During Mobilization, MR 19 Oct 1, 1942, supplemented by Change 1, dated Jan 22, 1943, and instructions issued by the Office of the Adjutant General, SPA 324-1 (1-22-43). PRI Joint Induction Procedure of the Army, Navy, Marine Corps and Coast Guard defined the physical standards in force at induction stations during the period represented by these data.

LEADING CAUSES OF REJECTION

The chart is based on the data of table 2 and shows, by the lengths of horizontal bars, the relative importance of the ten leading causes of rejection among white and among Negro 18 and 19 year old registrants. Later sections of this paper will discuss each of these defects.

TABLE 1—Rejection Rates of 18 and 19 Year Old Registrants*
Rejections per Hundred Examined

	Rejection Rate		
	White and Negro	White†	Negro
Local board	5.2	1.3	16.5
Induction Station‡	21.3	20.4	41.8
Combined rate§	23.4	21.8	45.6

Based on a sample of 4,385 reports of physical examination and induction D S S Form 221 for 18 and 19 year old registrants. Registrants deferred at local board for reasons other than physical or mental defects are not included.
* Includes all races other than Negro.
† Based on the number of registrants who passed a local board physical examination and were forwarded to an induction station for examination.
‡ Based on the number of registrants examined at local board who were rejected at local board or induction station.

groups in detail. The following discussion is concerned only with certain general relationships.

The most striking difference between the two racial groups concerns the high rate of rejections among Negroes for educational deficiency and for syphilis. Educational deficiency accounted for 121.7 rejections per thousand Negro youths examined, or for 26.7 per cent of all Negro rejections. Syphilis accounted for 112.0 rejections per thousand examined, or for 24.6 per cent of all Negro rejections. The two conditions together accounted for slightly more than half of all rejections of Negro youths. Eye defects and mental disease, the leading causes of rejection among white youths, ranked seventh and fourth respectively among Negro youths.

Other defects appear on each of the two lists of ten leading causes of rejection but with different rank among white youths and Negroes. Thus, musculoskeletal defects are in third place among white youths and in fifth place among Negroes, and cardiovascular defects are fourth in importance among white youths and third among Negroes. Ear defects and underweight appear on the list of ten leading causes of rejection among white youths but are not important as causes of rejection among Negroes. Conversely, syphilis and tuberculosis, listed among the first ten causes of rejection for Negroes, are lower in order of importance among white youths. Further comparative data may be found in table 2 and in the discussion which follows.

Similar lists are obtained by ranking the ten leading causes of rejection among registrants 20 years of age and older as shown on D S S Form 221 representing examinations made in the same period. Tuberculosis stands in ninth place and syphilis in tenth among white youths 20 years of age and older, displacing underweight and mental deficiency. Among Negroes, tuberculosis is in ninth place and mental deficiency in tenth, reversing their order in the 18-19 year age group. Among older Negroes syphilis is the leading cause of rejection, accounting for 28.7 per cent of all rejections. The other differences in rank of causes of rejection between the two age groups of each race are of minor importance.

During peacetime examinations made November 1940 through May 1941, when different physical standards were in force, the ten leading causes of rejection for white and Negro registrants combined, aged 21 to 36, were, in order, teeth, eyes, cardiovascular defects, musculoskeletal defects, venereal diseases, mental and nervous defects, hernia, ears, feet, and tuberculosis and other lung defects.¹ Since that time the standards affecting vision, teeth and educational qualifications have been revised, and increased attention has been devoted to the psychiatric examination.

CAUSE OF REJECTION AND INCIDENCE OF DEFECTS

Table 2 shows how frequently each of ninety-six diseases and defects was listed as cause of rejection and how frequently each was listed as present among all registrants examined, among white registrants and among Negro registrants. Data are expressed both in terms of the number of rejections and in terms of the number of cases per thousand registrants examined. The following discussion of the data of table 2 is largely limited to defects which are important as causes of rejection and to diseases or conditions whose occurrence can be prevented or controlled.

Eye defects, and in particular defective vision, have been a leading cause of rejection throughout the entire period of administration of the Selective Training and Service Act of 1940. The visual standards for general military service that became effective on Oct. 15, 1942 specified visual acuity of "not less than 20/200 in each eye without glasses if correctable to at least 20/40 in each eye." On Feb. 1, 1943, when joint Army-Navy induction stations began operation, the visual standards for general service were changed to "minimum vision of 20/70 in one eye and in the other eye at least 20/25 without glasses or acuity of vision of 20/25 with both eyes open without glasses, provided the vision in the worse eye is not less than 20/70."³ These data represent examinations made under both sets of standards. Some of the youths shown here as rejected for general military service because of eye defects were inducted for limited military service. Eye defects were cause of rejection of 44.9 registrants per thousand examined and were noted as present in 101.5 registrants per thousand examined. They were much more important as causes of rejection and in total incidence among white youths than among Negroes.

Ten leading causes of rejection by race, 18-19 year old registrants December 1942, February 1943

Ear defects, most of them specified as otitis media or as defects of the tympanic membranes (presented in table 2 under "other ear defects") were more prevalent and were more important as causes of rejection among white youths than among Negroes. This agrees with data for older registrants in this and other time period.

3 Instructions issued by the Office of the Adjutant General 51A 324 71 (1 22 43) PR I

Most of the rejections for ear defects occurred at induction station examination.

Dental defects were numerous particularly in white registrants but they were unimportant as cause of rejection during this time period. Before February 1942 when the standards for general military service

good musculature, are free from gross dental infections and have a minimum requirement of an edentulous upper jaw and/or an edentulous lower jaw, corrected or correctable by a full denture or dentures."

Tuberculosis is one of the defect groups in which Negroes have higher rates of incidence and higher

† Includes all races other than Negro. Less than 0.05 per thousand.

specified that a man must have three pairs of opposing natural masticators and three pairs of opposing natural incisors, the number of men disqualified because of missing teeth was so large as to make dental defects the leading cause of rejection. The standards in effect during the time period under discussion authorized induction of "individuals who are well nourished of

rejection rates than white registrants. When tuberculosis was present it was usually entered as the cause of rejection. It accounted for the rejection of 97 Negroes per thousand examined and of 66 white registrants per thousand examined. At induction stations where most of the tuberculosis rejections occurred, diagnoses could be based on the chest x-ray examina-

tions made routinely of all registrants. Local boards were authorized to reject registrants with an authentic history of active tuberculosis of any part of the body or treatment therefor within the preceding five years.

Cardiovascular disorders were also more frequently found in Negro youths than in white youths in particular valvular heart diseases and hypertension. This is in agreement with experience with older groups of registrants. Most of the rejections for cardiovascular conditions took place at induction stations.

Hernia was more often a cause of rejection among Negroes than among white persons. A part of this difference was due to the more frequent occurrence of umbilical hernias in Negroes. The physical standards provided that relaxed inguinal rings in themselves were not to be considered as a cause of rejection unless there was a definite protrusion of an abdominal viscus into a hernial sac. Relaxed inguinal rings were more frequently noted in white registrants than among Negroes.

In September 1942 the War Department announced that the Army would accept men with uncomplicated gonorrhea in a number not to exceed 2 per cent of the daily induction at each induction station for each

language difficulties have been inducted and given special training. Because facilities for special training are limited, quotas had to be set on the number of educationally deficient registrants who could be inducted.

Mention has already been made of the importance of mental disease as a cause of rejection. Although as a cause of rejection among Negroes it is outranked by educational deficiency and by syphilis, the rejection rate and the incidence for Negroes is slightly higher than the corresponding rates for white persons. The title "grave mental and personality disorders" includes schizophrenia or dementia precox, paranoia and related psychoses. The title "major abnormalities of mood" includes manic-depressive psychosis and cyclothymic disorders. "Psychopathic personality" includes constitutional psychopathic inferiority, criminal record and sexual psychopathy. "Psychoneurotic disorders" includes the various manifestations of psychoneurosis and certain psychosomatic disorders, including neurocirculatory asthenia, functional gastrointestinal syndrome, stuttering, stammering and tics. Inebriety and drug addiction are rarely recorded in this age group but increase in prevalence with advancing age.

A large proportion of the registrants with neurologic defects were rejected at local board physical examination, in part because a number of neurologic defects appear on the list of manifestly disqualifying defects and in part because of the use of information available in the registrant's community for establishing or confirming diagnoses of epilepsy or other disease of the nervous system.

Somewhat less than half of the rejections for musculoskeletal defects took place at local board examination. Many terms descriptive of bone, muscle and joint disorders appear in the list of manifestly disqualifying defects. Defects resulting from injury are more numerous than other categories of musculoskeletal defects. They include limited motion of joints, malunion of a fracture with bowing, shortening or deformity, and scars that result in contracture.

Underweight and overweight were more common among white youths than among Negro youths. No data were recorded on the examination form to show how frequently this or any other defect could be presumed to be the result of malnutrition. Entries on the physical examination form were usually restricted to objective findings with only infrequent references to history or to the cause of the condition under discussion.

REJECTION RATES BY OCCUPATION

Table 3 permits comparison of the rejection rates in nine broad occupation groups. Among white youths, craftsmen, foremen and kindred workers (comprising skilled workers) had the lowest rejection rate, 19.9 rejections per hundred examined, farmers, with 36.4, and emergency workers, with 37.2 rejections per hundred examined, had the highest rates of rejection. Among Negroes, proprietors, clerical, sales and kindred workers, with 26.9 rejections per hundred, and students with 31.6 per hundred examined, had the lowest rejection rates, farmers, with 58.0 rejections per hundred, had the highest rejection rates. Data on causes of rejection in the various occupation groups have not as yet been tabulated for this age group.

SUMMARY

The ten leading causes of rejection among white 18 and 19 year old Selective Service registrants were in decreasing order of occurrence eye defects, mental

† Insufficient data for calculation of rate

race, the proportion to be determined by available hospital facilities. During February 1943 the induction of registrants with uncomplicated syphilis began. Previously these diseases had been cause for rejection. Syphilis was recognized in the majority of cases by the result of serologic test of the blood sample drawn by the local board physician. The striking difference between rejection rates for white registrants and for Negroes has already been commented on. The increase in incidence of syphilis with advancing age is brought out in the tabulations of serologic test report forms compiled and published by the U. S. Public Health Service in cooperation with the Selective Service System.⁴ A large proportion of the registrants found to have gonorrhea were inducted. Gonorrhea was more prevalent and accounted for more rejections among Negroes than among white registrants.

Determination of educational deficiency and of mental deficiency was made at induction stations on the basis of psychometric tests designed to measure the individual's capacity to absorb basic training. Large numbers of registrants with meager schooling or with

4 U. S. Public Health Service. Results of Serological Blood Tests for Syphilis on Selective Service Registrants, 2 volumes multilithed. Venereal Disease Division, U. S. P. H. S., 1942. Volume 1 is based on the first million reports received during the period Nov. 1, 1940 to April 15, 1941; volume 2 is based on the second million reports received during the period April 16, 1941 to Aug. 31, 1941 for registrants examined in accordance with the Selective Training and Service Act of 1940.

disease musculoskeletal defects cardiovascular defects, ear defects hernia neurologic defects educational deficiency underweight and mental deficiency. For 18 and 19 year old Negroes the ten leading causes of rejection were educational deficiency syphilis cardiovascular defects mental disease musculoskeletal defects hernia eye defects neurologic defects mental deficiency and tuberculosis. Half of the rejections of Negro youths resulted from educational deficiency or from syphilis. These data are based on local board and induction station examinations made during December 1942 and January and February 1943.

In the following broad groups of defects white youths had higher rejection rates than Negroes—eyes, ears, nose, kidneys, nervous system, feet, endocrines, overweight and underweight.

In the following broad groups of defects, Negro youths had higher rejection rates than white youths—tuberculosis cardiovascular disease hernia genital disease syphilis gonorrhea skin disease educational deficiency mental deficiency and mental disease.

POLIOMYELITIS AND PREGNANCY

WITH SPECIAL REFERENCE TO THE FAILURE
OF FETAL INFECTION

TWO HITHERTO UNREPORTED CASES IN ONE OF
WHICH THE HUMAN FETAL SPINAL CORD
WAS EXAMINED FOR THE VIRUS

PAUL H. HARMON, PH.D., M.D.

SAYRE, PA.

AND

ARCHIBALD HOYNE, M.D.

CHICAGO

This report will add further evidence to the thesis that now appears to be well established that pregnancy has little if any, influence on the course of poliomyelitis in a paralyzed mother and conversely, that in utero infection of the fetus occurs with rarity if at all. The corollary that acute poliomyelitis in the mother has no effect on the fetus is questioned by one of our cases in which fetal death occurred in utero presumably as a result of asphyxia associated with faulty oxygenation of the maternal blood during the acute course of bulbar poliomyelitis. In the past several years several reports and studies of this question have been published which have established the two facts first mentioned almost beyond doubt. The reason for the report of one of the cases described is that an opportunity was present to examine the fetal spinal cord for virus. The results of this examination were negative, which would add further evidence in favor of the contention that the virus of poliomyelitis under the natural occurrence of these events simultaneously in man does not pass from mother to child. There are probably several reasons to explain this phenomenon. As is generally agreed by many investigators¹ the

virus of poliomyelitis is found with rarity if at all in the circulating blood stream of a victim of this disease. Presumably, to favor transmission of a virus through the placenta the infectious agent should gain ready access to the blood stream. There is ample evidence both clinical and experimental to show that, in other conditions in which it is known that a submicroscopic virus is present in the blood stream the related virus passes through the placenta and may infect the fetus. These experimental data include the observation of Levaditi, Harvier and Nicolau² who demonstrated that one of the viruses from encephalitis in man can when inoculated into rabbits pass the placenta and localize in the fetal nervous system. Goodpasture³ has also demonstrated passage of vaccinia through the placenta and in the same review considers the evidence to have conclusively shown that the viruses of measles, chickenpox and lymphocytic choriomeningitis can regularly pass the placenta. Hirano⁴ demonstrated that vaccine virus can penetrate the placental barrier. Traub⁵ has shown that the virus of lymphocytic choriomeningitis can pass readily from the mother to the in utero young and the latter can harbor the infection acquired congenitally for a prolonged time.

In the clinical literature Welz⁶ reported a total mortality of 66 per cent in his series of 21 cases of maternal influenza. Abt and Townsend⁷ each reported single cases of premature infants born of mothers suffering from influenza who showed signs of the disease at birth. Kosmak⁸ likewise reported fetal deaths in cases of maternal influenza. In the total child cases just referred to no autopsies which included virus studies were reported. Marinesco⁹ and Kononowa¹⁰ each reported fatalities in infants born of mothers suffering from epidemic encephalitis. Each of these 2 latter cases were instances in which microscopic lesions of encephalitis were demonstrated in the brain of the fetus but no virus studies were reported. There are many other reports in the literature of fatalities and cases in the fetus issuing from women the victims of epidemic encephalitis, but the latter cases do not contain data indicating that examination of the central nervous system of the fetus was made and therefore are not valuable to corroborate the point at issue. The virus of encephalitis at least of the equine and related types which are probably responsible for much of the 'sporadic' and epidemic encephalitis in man differ in two important respects from poliomyelitis virus—the former occurring in the blood stream of at least the animal intermediate hosts and in the cerebrospinal fluid in man.¹¹

Experiments with the Virus of Poliomyelitis. *J Exper Med* 51: 193-1940. Cordon F B and Lennette E. The Blood Stream in Experimental Poliomyelitis. *Infect Dis* 64: 97-1939.

Two thorough studies of the obstetric experience of women in whom poliomyelitis occurred during pregnancy have been reported in recent years. The antecedent literature bearing on questions pertinent under this topic were thoroughly reviewed in both these reports, and thus no attempt will be made to summarize the literature bearing on this question here. The first of these reports was written by Brahdý and Lenarsky,¹² the subjects being 2 normal infants, 1 at term and the other premature, born of mothers suffering from acute poliomyelitis. These authors reported 1 case of their own and summarized others in the literature which showed that poliomyelitis may occur early in pregnancy as well as later. Their own case and others quoted from the literature showed that poliomyelitis had no influence on pregnancy and that as a result a normal issue was to be expected from mothers who developed this disease during the latter months of pregnancy. The most recent study is that of Kleinberg and Horwitz¹³ who studied all aspects of this topic, including the types of pelvic deformity resulting in women previously paralyzed by acute poliomyelitis and the obstetric histories of pregnancy in women previously paralyzed by poliomyelitis. In addition to summarizing cases of pregnancy complicated by an acute attack of anterior poliomyelitis from the literature they added 13 hitherto unreported cases. A review of the total of 29 such cases demonstrates that a normal child was obtained in 24 instances (82.8 per cent). The causes of stillbirth and of early fetal death which were recorded in 4 cases (13.8 per cent) were associated with prematurity. There was no evidence of postpoliomyelitic paralysis in any of the premature offspring or the children who died shortly after birth. In 1 case (Miller¹⁴) to be found in the literature a child with bilateral clubbed feet was delivered. The appearance of these feet was that of bilateral congenital clubbed feet the occurrence of which was probably unrelated to poliomyelitis in pregnancy. Kleinberg and Horwitz conclude that, "notwithstanding severe paralysis involving the abdominal and extremity muscles and occurring during gestation, a normal course of pregnancy and labor and normal offspring may be anticipated."

REPORT OF CASES

CASE 1—R. B., a woman aged 30, admitted to the Chicago Municipal Contagious Disease Hospital on Aug. 29, 1936, had first become ill five days previously with "cold and fever," according to the history obtained on admission. Two days later the left arm was paralyzed and the patient first experienced dyspnea. The patient was said to have been afebrile since the onset of paralysis three days prior to admission. The family physician had no opportunity to examine the patient until the morning of the day of admission, on which occasion he made a diagnosis of a six months pregnancy and stated that the fetal heart tones were then present.

On admission the patient was dyspneic and cyanotic, respirations being carried out by the abdominal and accessory respiratory muscles. The alae nasi dilated on inspiration. The patient was obviously fatigued. There was extensive paralysis in the left arm, and no reflexes were elicited in this member. The neck was rigid and the voice hoarse. Examination of the spinal fluid on admission showed a clear fluid under a

moderate increase in pressure. Eighty cells per cubic millimeter were counted and the Ross-Jones test showed a moderate increase in globulin. On the day following admission the patient exhibited more exhaustion and was then placed in the respirator with some betterment in the cyanosis. On the third and fourth days of hospitalization the fetal heart tones were still heard and the patient was in and out of the respirator.

From the fifth hospital day a uterine souffle was heard but no fetal heart tones could be detected. On the sixth hospital day no fetal heart tones were detected and the patient was beginning to exhibit some abdominal pains. These, however, quickly subsided and the patient remained about the same until the tenth day, when she began to have frequent abdominal pains, exhibited some slight bloody vaginal discharge and during the course of the day began to have labor pains, which increased in severity and intensity. The cervix dilated during the day and delivery of a stillborn fetus occurred during the evening. As far as could be told from the examination of the fetus, which was slightly macerated, it had been dead for at least forty-eight hours and possibly longer. On the twelfth hospital day it was noted that the mother was breathing more easily on the occasions when she was out of the respirator, and on the twenty-first hospital day she was allowed out of the respirator the greater part of the day. From this point she pursued an uneventful course but continued to exhibit residual paralysis in the left upper extremity. Postmortem examination of the child was carried out on the same day as the stillbirth. The spinal cord was removed and preserved in 50 per cent glycerin.

Intracerebral inoculation of a *Macacus rhesus* monkey with the supernatant fluid from the ground emulsion of 0.3 Gm of the fetal spinal cord was performed after preservation of the cord at 5 C for forty days in 50 per cent glycerin. Daily observations were made of the rectal temperature of this animal for the ensuing twenty-six days. On four single observations a rise of almost 2 degrees was noted from a previous average normal of 101.6 F, but the animal showed no consistent signs which might be attributable to poliomyelitic infection. On the twenty-sixth day the monkey was killed and the cord removed for microscopic study. Sections prepared at four levels of the spinal cord failed to show any lesions characteristic of the disease. An attempt at further passage of the latter material into a second monkey produced no symptoms.

CASE 2—R. C., a woman aged 32, was in good health until during the eighth month of pregnancy, when on Sept. 3, 1942 she was seized with nausea and vomiting, which continued for three days. The attending physician did not consider the possibility of poliomyelitis until the fourth day of illness, when the patient suddenly noticed that she could not elevate the right leg and at the same time noted weakness in the right arm. She also experienced a "choking sensation" in the throat and at the same time dysarthria and dysphagia were present. For the ensuing several days she experienced severe backache. This disappeared with back strapping and did not subsequently return. The patient was subsequently referred to another hospital, where she received the hot moist pack treatments for paralysis (Kenny method). The results from this treatment were considered to be only partially successful. Symptomatic relief could not be credited to the treatment, as the patient was free from pain at the time when the packs were begun. She was admitted to the Guthrie Clinic and Robert Packer Hospital on Dec. 26, 1942, at which time a residual paralysis was noted in the muscles of the right shoulder girdle, in the left leg and in the entire lower right extremity. Extensive muscle atrophy was noted in the right shoulder girdle and throughout the entire lower extremity. The paralysis in the right upper extremity included the rhomboideus major and minor muscles, the trapezius, latissimus dorsi and a portion of the serratus anterior, which resulted in definite winging and dropping of the scapula on attempts to move the upper extremity. Contractures were present in the trapezius. Clinging of the toes was noted in the left foot on attempts at dorsiflexion, and contractures were present in the short flexors of this foot, producing a pes cavus. The anterior and posterior

tibial muscles were functioning in this foot but were weak since the foot went into valgus on attempts at dorsiflexion. The right lower extremity was completely flail except for moderate action of the gluteus maximus and a faint trace of action in the short flexors of the arm.

Regarding the patient's obstetric experience, induction of labor was performed on Sept. 7, 1942 and delivery of a normal viable child resulted. To date ten months after birth the child is progressing well and is apparently normal. There is no evidence of paralysis in the offspring.

COMMENT

CASE 2 illustrates the usual and average experience of the pregnant patient who requires acute poliomyelitis. There is a normal issue assisted by a minimum of operative intervention which is of the same type as required in nonparalyzed gravid patients. Both this case and the previous one lend weight to the accumulating mass of evidence in the literature that congenital poliomyelitis does not occur. The summary of the experience of other physicians with this complication as related in the reports of Brahm and Lenarsky and Kleinberg and Horwitz are in agreement on this point. In this connection Kleinberg and Horwitz say:

We conclude that pregnancy complicated by acute anterior poliomyelitis may be anticipated to progress normally with a normal termination of labor and with a normal offspring. The involuntary contractions of the uterus and the ability of the uterus to expel its contents spontaneously observed also in patients paralyzed by cord tumors, spondylitis and vertebral fracture are due to the fact known to physiologists that the uterus has an independent nerve supply and will contract not only after the spinal cord is transected but even after its sympathetic nerve supply is extirpated. There was no instance of intrauterine poliomyelitis in these 29 cases. The passive immunity of the offspring derived from the mother does not persist for long since a number of cases of acute anterior poliomyelitis under the age of 1 month (earliest 9 days) have been reported. An analysis of 243 patients who became pregnant one year or more subsequent to an acute attack of anterior poliomyelitis indicates that a normal and uneventful pregnancy and labor with a normal offspring may be anticipated in these cases. There is no indication for interruption of the pregnancy at any stage except for those reasons that would be operative also in nonparalytic females. The complications prior to and following delivery in paralytic females are, on the percentage basis almost identical with those in nonparalytic females.

The outcome in case 1 does demonstrate that death of the fetus may occur under certain circumstances during the course of acute poliomyelitis. The cause of fetal death in this instance was not ascertained with certainty but it is highly probable from the clinical course of this case, during which time the mother definitely demonstrated anoxia in association with nonfatal bulbar poliomyelitis that it was an asphyxial death. The problems raised in this connection are of considerable weight. Owing to the average excellent outcome in most cases of poliomyelitis one is reluctant to recommend operative delivery since it is apparent from a perusal of the literature that it has been unnecessarily employed in the past.

However, it would appear that delivery by cesarean section (preferably laparotrachelotomy under local anesthesia and without giving drugs which might create further maternal and fetal anoxia e. g. morphine) would be indicated in a restricted number of cases in which the outcome as regards the mother is in doubt

but where there is great desire to secure a viable fetus. Such cases would be those of the general type as illustrated by our case 1. However, if such a procedure had been adopted it is even somewhat questionable as to whether the outcome would have been different in our case, as fetal death occurred shortly after hospitalization and occurred at a time when the condition of the mother, although critical was not unduly alarming.

The importance of our case 1 lies in the attempt which was made to demonstrate the presence of virus in the fetal spinal cord. The conditions under which this attempt was made were as ideal as possible under the circumstances. It is improbable that the delay between removal of the cord and the inoculation of the monkey (forty days) had any bearing on the negative result obtained as it is known that poliomyelitis virus remains viable in the spinal cord preserved in 50 per cent glycerin for many years.

The fact that virus is not found in the fetal spinal cord is to be expected rather than the reverse as several events would have to be postulated concerning which facts are in disagreement. The virus is not found in the blood with any regularity, if at all, in either human patients or in simians in which the disease is experimentally induced. Even if it should be assumed that the virus could pass the placenta which is indicated as a possibility, provided the virus could gain access to the blood stream (analogy to other viruses) it would still have to be assumed that some irritative process was at work in the central nervous system of the fetus in order for infection to occur since it is known that large quantities of the virus of poliomyelitis may be present in the blood stream in the absence of central nervous system irritation without causing subsequent infection. This situation results because of the impermeability of the blood cerebrospinal fluid barrier to the poliomyelitis virus. This barrier can be upset under certain experimental conditions and possibly in human patients (e. g., a spinal puncture performed on some rare occasions when virus is present in the blood stream). The special experimental conditions include the production of sterile abscesses in the brain (e. g., by starch) the inflammation of an aseptic meningitis (as produced by the intraspinal injection of horse serum) and other circumstances that result in disturbed equilibrium in the barrier.

CONCLUSIONS

Our case 2 demonstrated an outcome which is usual and to be expected in this complicated situation, i. e. apparently little or no effect by pregnancy on the extent of paralysis in the mother (?) and a viable nonparalyzed fetus. This case and those previously reported in the literature would tend to demonstrate that congenital poliomyelitis does not occur.

Our case 1 demonstrates that under certain circumstances death of the fetus may occur presumably from asphyxia. Whether operative delivery in our case 1 would have resulted in a different outcome is problematic, but the case of impending respiratory paralysis in the mother resulting in maternal and fetal anoxia is apparently the only situation which would indicate operative delivery. An attempt to isolate the virus of poliomyelitis from the fetal spinal cord in case 1 resulted negatively. This outcome although not proof positive that virus was not present in the fetal spinal cord could be interpreted in that way.

CONCEPTS OF MUSCLE DYSFUNCTION IN POLIOMYELITIS

BASED ON ELECTROMYOGRAPHIC STUDIES

ARTHUR L. WATKINS, MD

MARY A. B. BRAZIER, PhD

BOSTON

AND

LIEUTENANT COMMANDER ROBERT S. SCHWAB
(MC), USNR

The importance of muscle "spasm" as a symptom of acute poliomyelitis has received emphasis since the Kenny¹ concepts of the symptomatology and treatment of this disease have come into prominence. Muscular pain, tenderness and shortening have been recognized for many years as characteristic features of acute poliomyelitis and have been described by different authors, particularly by Lovett² and by Ober,³ who have advocated treatment with local heat in the form of hot fomentations and by gentle passive movements followed by active muscle reeducation. In recent studies of "spasm" Schwartz and his associates⁴ have recorded electrical potentials from muscles in cases of acute poliomyelitis with a cathode ray oscillograph and found widespread hyperirritability to stretching not only in muscles which appeared to be in "spasm" but also in their antagonists and in those clinically unaffected.

In addition to muscular "spasm," Kenny has emphasized functional paralyses of the antagonistic muscles, which she believes may not be truly affected by the disease but "mentally alienated." Kenny also describes another disorder of muscular function in poliomyelitis, "incoordination," which she ascribes to a "condition arising in the central nervous system in which the regulation and direction of nerve impulses is upset so that the natural rhythmic and cooperative action of associated muscles is disturbed."⁵

In order further to elucidate these concepts of muscle "spasm," "mental alienation" and "incoordination" we have studied the electrical discharges of muscles while at rest, during passive stretching and during voluntary contraction both in the early and in the late stages of poliomyelitis. The observations have been compared with similar studies on normal controls and on patients having traumatic lesions of peripheral nerves. These investigations have yielded information on the disorder of muscle function in poliomyelitis and have led us to conclude that the Kenny concepts of muscle involvement in this disease, although the basis of an excellent type of treatment, are inadequate as a physiologic explanation of the dysfunction present.

METHODS OF STUDY

Electromyograms were recorded by a standard ink-writing Grass electroencephalographic apparatus. The full details of the methods employed have been described elsewhere.⁶

Two different electrode techniques have been used in this work. These consisted of: 1. Surface electrodes, made from solder disks approximately 1 cm in diameter, applied to the skin over the muscle with electrode paste and adhesive tape. A third electrode is placed on a neutral point to act as a ground. 2. Coaxial needle electrodes made by inserting an insulated core into a hypodermic needle (gauge 24). These are placed in the substance of the muscle and the outside of the needle is grounded. In some experiments synchronous recordings were made from the same muscle by the two electrode techniques.

Insulated copper wire from the electrodes feeds the current through shielded leads into the preamplifier stage of a standard electroencephalographic apparatus. In the second stage of the apparatus the filters are arranged so as to pass high frequency potential changes, and the degree of amplification is varied according to the amount of electrical discharge. Calibrations with a standard input are made with every recording so that at any moment an exact assessment can be made of the actual voltages elicited from the muscle. The degree of amplification used was never greater than 1 cm deflection for 100 microvolts, at which setting no electrical activity is recordable from normal muscles in relaxation.

The final recording is made with an ink-writing oscillograph on paper, which is usually run through at a speed of 6 cm per second; this speed of paper has been found to give a satisfactory recording of the range of frequencies found in muscle activity.

CASE MATERIAL

Eleven cases of poliomyelitis were studied in various stages of the disease process over a period of two years. The results were compared with recordings from normal controls from patients with peripheral nerve injuries including war wounds from patients with infectious polyneuritis and from patients with muscle spasm secondary to fractures. The electrical activity of muscles was studied in positions of maximum relaxation during passive stretching and during voluntary contraction. In some cases correlative studies were done of the electrical excitability as measured by voltage-capacity curves and of work performance as recorded by an ergograph, following methods previously described.⁷

RESULTS

Spontaneous Electrical Discharges in Resting Muscles—In normal cooperative persons we have observed as has Hofer,⁷ that when efforts are made to relax completely the musculature of an extremity by comfortable positioning and support, no action potentials are recorded. Hofer's technique was similar to that used in our investigations. The occurrence then of spontaneous discharges from relaxed muscles examined by this technique indicates some abnormality and forms a point of study in cases of poliomyelitis.

Electromyograms were therefore recorded from muscles which were tender and painful on palpation or stretching (clinically in spasm) and also from weak muscles not showing "spasm". In some instances the antagonists of the muscles exhibiting clinical evidence of "spasm" were the weaker muscles although this was not uniformly true.

In the acute stage of the disease some low voltage discharges were found at rest but only from the most weakened muscles and frequently not at all from the posterior muscles of the trunk and lower extremities although clinically these muscles were quite tender and painful on stretching (fig 1 A).

In the later stages of the disease particularly beginning about the third month in cases with considerable paresis we have noted in the resting muscles the onset of spontaneous electrical discharges of a more striking character (fig 1 B). These potentials were of higher voltage and were somewhat suggestive of motor unit activity as described by Weddell, Feinstein and Pattle.⁵ The muscles which clinically showed the most loss of power gave rise to these discharges more frequently than

Fig 1—Spontaneous discharges in two resting muscles in poliomyelitis. The anterior tibial is the weaker muscle whereas the gastrocnemius shows the most spasm clinically. A three days after onset B three months later C five months after onset. Ink writing on cellophane surface electrode technique and calibration the same in all tracings.

did their antagonists which usually showed clinical "spasm". This electrical activity appeared to be an index of weakness and could not be correlated with clinical "spasm". Similar spontaneous discharges have been found to persist for many months particularly in muscles with continuous improvement in function. In one case followed for a year and a half with good restoration of muscle power (as indicated by ergographic studies and manual tests of strength) the discharges were still present on the final examination although there was no pain, tenderness or other evidence of "spasm" clinically (fig 2). In other cases, with only slight restoration of function electrical discharges gradually lessened in incidence (fig 1 C) and finally disappeared when the improvement ceased.

From these observations we conclude that the foregoing examples of electrical discharge are manifestations of a recovery process. This hypothesis is further substantiated by muscle studies during regeneration of traumatized peripheral nerves. From these muscles we

have recorded similar electrical discharges. They appeared as an early sign of regeneration and persisted throughout the period of improving function (fig 3).

Response of Muscles to Passive Stretching—The response of muscles to passive stretching during the

BICEPS

Fig 2—Spontaneous discharges in resting muscle with good recovery of strength one and one half years after onset of poliomyelitis.

RESTING MUSCLE

Fig 3—Spontaneous discharge from resting muscle during regenerative period after brachial plexus injury.

early and late stages of poliomyelitis was studied by electromyography. In these tests the muscles were stretched through the full arc of motion by a quick passive movement. During the acute stage this frequently brought out electrical discharges of a voltage higher than any which can be elicited from normal muscle by such a manipulation (fig 4). Moreover these discharges would persist for some time after the passive stretching had been released. In many instances a similar response was obtained by placing muscles under a slight increase of tension through adjusting the position of the limb. The appearance of these discharges was similar to those which we have recorded in patients with muscle spasm associated with painful joint motion following a recent fracture (fig 5).

Although the voltage of the discharges gave an indication of the degree of irritability to passive stretching we found that this abnormality occurred primarily in the partially paralyzed muscles and only minimally in

PASSIVE PLANTAR FLEXION

Fig 4—Electrical response to passive stretching in acute poliomyelitis.

SPONTANEOUS DISCHARGE IN RESTING MUSCLE

Fig 5—Muscle spasm in case of fractured elbow.

unparalyzed muscles which showed clinical "spasm". When there was equal degree of weakness in a pair of antagonistic muscles we found equal irritability on stretching as recorded electrically even though clinically one muscle showed more "spasm". We conclude therefore that when one muscle is functionally weaker than its antagonist the weaker muscle will show the greater

⁵ Weddell, Graham, Feinstein, Bertram, and Pattle, R. E. Clinical Application of Electromyography. *Lancet* 1: 26-239 (Feb 20) 1947.

abnormality electromyographically. That this weakness is not due to "alienation," as suggested by Kenny,¹ but to greater involvement by the disease process was further substantiated by loss of electrical excitability in the weak muscles as measured by voltage-capacity curves.⁴

Fig 6—Action potentials during ergographic tests. Recordings from biceps: A, four months after onset of poliomyelitis; B, seven months; C, fifteen months.

In the later stages during improvement of motor power, passive stretching accentuated the spontaneous discharges present in the weak muscles at rest. Again, the irritability was correlated with the degree of weakness and not with the degree of shortening, tenderness or other clinical sign of "spasm."

In the long-standing cases, several years after the onset, no abnormal response to stretching was obtained in paralyzed muscles or in those which were shortened by contracture but still functioning.

Electromyograms During Voluntary Contractions.—Action potentials were studied during voluntary contractions such as are required in an ergographic test.⁶ The voltage of these discharges was found to be proportional to the degree of strength and gave indication of the rate of restoration of function (fig 6). There was, however, no constant correlation between the voltage of spontaneous discharges at rest and that of the action potentials.

Fig 7—Simultaneous action potentials in opposing muscles during active flexion and extension of the ankle in poliomyelitis.

Fig 8—Synchronous action potentials in opposing muscles during active knee extension in poliomyelitis.

Observations were made during active movement, with simultaneous recording from antagonist and protagonist. By reciprocal innervation, inhibition of antagonists occurs during coordinated voluntary movements. Studying pairs of muscles, such as the anterior tibials and gastrocnemius, or the quadriceps and hamstrings, we found in our patients with poliomyelitis that, on flexion or extension of the knee or ankle, the two

opposing muscles were activated simultaneously (fig 7). This phenomenon occurred in patients who were receiving muscle reeducation and were being specifically trained to avoid such "incoordination." In these cases simultaneous contraction of opposing muscles could be detected electrically, although not suspected on observation of the muscles in action.

In addition to the simultaneous action of opposing muscles we have observed in many instances that individual diphasic spikes were discharged synchronously in the pair of opposing muscles. This synchrony was apparent in the spontaneous discharges from resting muscles at times but was not consistently present. During a single examination, periods of synchronous discharges would come and go, being most frequently elicited by voluntary contractions (fig 8). These synchronous action potentials have been found in

Fig 9—Synchronous action potentials in opposing weak muscles during active dorsiflexion fifteen years after onset of poliomyelitis.

Fig 10—Spontaneous discharges in resting muscles during regeneration in brachial plexus injury. Note synchrony of individual spikes in upper two records.

Fig 11—Simultaneous discharges in opposing muscles during active flexion of elbow after regeneration from brachial plexus injury.

patients whose poliomyelitis had occurred ten or fifteen years previously, as well as in patients in the early convalescent stage, and seem unrelated to the presence or absence of "spasm" in one or both of the muscles tested (fig 9).

In studies of muscles during regeneration following traumatic peripheral nerve lesions we have observed similar synchrony of electrical discharges. The large diphasic spikes recorded from resting muscles have been found to occur synchronously in separate muscles at times and also asynchronously during the same recording period. This was illustrated in the case of a brachial plexus injury in which discharges occurred synchronously in two opposing muscles of the lower arm, whereas the discharges from the upper arm were asynchronous (fig 10). In the same patient, on voluntary flexion of the elbow there were simultaneous action potentials from the biceps, triceps and deltoid without definite synchrony of individual spikes (fig 11).

This synchronization of individual discharges is such an unexpected finding that we took every precaution to rule out the possibility of artefact. Since this

synchronization was not continuous but intermittent it seemed unlikely that it could be due to the picking up by one amplifier of currents from its neighbor in the examining room. Furthermore it was never found in normal controls. Careful efforts were made however, to eliminate any possibility of such extraneous effects. Two different electrode systems were used: the surface electrodes were replaced by corvial needles and the recording was run first on the push-pull circuit and then on the grounded circuit. Shifting of the electrodes from one position on the muscle to another was also tried. All these experiments led us to the same conclusion: that this type of synchronous discharge is a neuromuscular phenomenon.

These observations indicate that an important feature of poliomyelitis is a disorganization of normal reciprocal innervation. The similarity of findings in peripheral nerve injuries suggests that this disorganization is a manifestation of regeneration in the lower motor neuron.

COMMENT

Relatively little electrical activity was found in affected muscles during the acute stage of poliomyelitis as compared with that observed two or three months after the onset. These patients promptly received hot fomentations of the type described by Kenny,¹ with consequent reduction in muscle sensitivity.

The electrical response of muscles to passive stretching in our poliomyelitis patients resembled that seen in other conditions in which muscle spasm acted as a protective mechanism in response to pain, as in acute back strain or painful joints associated with arthritis or with trauma. This similarity may indicate that the response is nonspecific as far as a neurologic disease is concerned being a reflex phenomenon stimulated by pain.

The spontaneous electrical discharges at rest, however, appeared to be unrelated to pain or other clinical evidence of muscle spasm. The correlation in this instance was with the degree of muscle weakness and consequently was an index of involvement of the neuromuscular system by the disease process. In completely paralyzed muscles, however, or in muscles much weakened in which there was no evidence of improving function these spontaneous discharges were not obtained.

Because of the limitations in the speed of recording by ink-writing oscillographs fibrillations of denervation are of too short duration to be recordable (1-2 milliseconds). The cathode ray oscillograph provides a more suitable recording speed for this purpose. Needle electrodes are unsatisfactory for detection of the fibrillations of denervation since they frequently act as an irritant to the muscle causing discharges which should be regarded as artefacts, these confuse the records of spontaneous activity in resting muscle.

In our work with an ink-writing oscillograph therefore, no fibrillations of denervation were recorded. The speed was however entirely suitable for registering motor unit activity, the spikes being usually of 5 to 10 milliseconds in duration.

In muscles showing such evidence of improving function as an increase in electrical excitability and in strength there were spontaneous electrical discharges which persisted at least as long as one and a half years. As this same type of electrical activity is also found in muscles supplied by regenerating peripheral nerves following suture it seems reasonable to conclude that the discharges from the muscles in poliomyelitis are manifestations of a regenerative process. When present in the acute stage it may, of course, represent the occur-

rence of degeneration rather than regeneration. The pattern of electrical discharges differs, however, in regard to frequency and voltage from that seen in progressive muscular atrophy, presumably an entirely degenerative disease. In the latter disease increased electrical activity is usually associated with loss of power and atrophy whereas in poliomyelitis it has been correlated with clinical improvement, the discharges disappearing when this ceased. These discharges may depend on the presence of a combination of functioning and nonfunctioning fibers in a muscle with a resultant hyperirritability on some chemical basis such as sensitivity to acetylcholine or they may represent motor neuron activity. Further experiments such as peripheral nerve blocks, might throw more light on this point. In any case the conclusion seems warranted that this electrical evidence of hyperirritability is not correlated with clinical signs of muscle 'spasm' and is probably an indication of neuromuscular regeneration.

The term muscle "spasm" is inadequate to describe the abnormalities revealed by electromyography and may even be misleading. Instead of a single condition we find that three types of abnormality are observable. The first is hyperirritability of the affected muscles to stretching as indicated objectively by electrical discharges and subjectively by pain during the acute stage of the disease. This may be a nonspecific reflex tension initiated by a painful stimulus. The cause of the pain is obscure. The hyperirritability may be due to invasion by the virus of the posterior roots, meninges or peripheral nerves and muscles.

Secondly, during the period of improving motor function muscle irritability, as evidenced by spontaneous discharges is not correlated clinically with pain, tenderness or shortening but with weakness and with electrical indication of regeneration.

Thirdly, the shortening or contracture of muscles which may persist for months or years after the onset is not associated with hyperirritability electrically and may be due to changes intrinsic to the muscle rather than to spinal cord disease.

The term 'mental alienation' seems unnecessary, for weakness or actual paralysis of muscles is probably due to specific lesions in the anterior horn cells. Loss of volitional control of muscles does occur without such anatomic lesions particularly after immobilization as for fractures and in association with painful movements. In our cases of poliomyelitis, however, weakness was always accompanied by objective signs of neuromuscular disease such as loss of electrical excitability or abnormal electromyograms. Whenever there was imbalance about a joint, such as results in an equinus or calcaneus deformity, we have observed a corresponding imbalance of involvement, the weaker muscle showing the greater electrical abnormalities. If paralyses unrelated to the cord lesion occur in poliomyelitis they would seem therefore to result from treatment such as immobilization or from failure to relieve pain rather than from "alienation" or some other speculative neuromuscular dysfunction specific to the disease process.

We have found objective evidence, however, of "incoordination" in poliomyelitis. The simultaneous activation of antagonists and agonists was a striking feature of our electrical recordings. This does not necessarily prove an abnormality of the nervous system as it is well recognized that individuals with weak muscles from any cause may contract all the muscles together in attempting movements beyond their strength. This is common clinical experience in the muscles of an

extremity immobilized for treatment of a simple fracture. In our cases however, the attempted movements were only minimal and specific muscle reeducation had been given to eliminate if possible, the simultaneous contraction of opposing muscles. Furthermore, those movements were painless. The actual synchrony of individual spikes in opposing muscles both at rest and during motion is a most unusual finding. This cannot be produced in normal muscles by voluntary attempts and indicates striking disorganization of the neuromuscular mechanism. The fact that this synchrony of muscle discharges was observed also during regeneration of peripheral nerves after injury leads us to believe that it is a phenomenon associated with a regenerative process. It is known that peripheral nerves do not function entirely normally after regeneration if the lesion has been severe enough to cause wallerian degeneration.⁹ For example, in many cases of facial paralysis of the common Bell's type coordinated individual muscle action is never regained and the muscles of the eye and mouth consequently function simultaneously with all voluntary movements. The so-called "incoordination" in patients with poliomyelitis may also be an example of abnormal function following regeneration. Although these studies do not rule out involvement of higher levels in the central nervous system, all the results obtained are explainable on a basis of a disordered peripheral neuromuscular mechanism.

SUMMARY

1 In poliomyelitis the term "muscle spasm" is inadequate to describe the complexity of dysfunction which is revealed by electromyography.

2 In the acute stage only muscles with some degree of paralysis discharge electrical potentials at rest, these electrical abnormalities are not correlated with the presence of clinical "spasm."

3 Partially paralyzed muscles are hyperirritable to passive stretching, as indicated by electrical discharges and pain, the muscle tension thus developed appears to be a reflex protective mechanism.

4 The electrical activity in paretic muscles at rest increases during the period of improving motor power, and the pattern of discharges corresponds with that seen in muscles during regeneration of peripheral nerves. When improvement in motor power ceases, spontaneous electrical discharges disappear.

5 No abnormal electrical activity is associated with the muscle contractures of the late stage of poliomyelitis, nor are any discharges present in completely paralyzed muscles.

6 The concept of "mental alienation" does not contribute to the explanation of paresis in our cases, since objective signs of a disease process were always present in the paretic antagonists of muscles in "spasm."

7 Increase of voltage of action potentials during successive eigographic tests is an index of recovery of motor power.

8 Of the three concepts of Kenny, the only one upheld by our objective measurements is that of "incoordination," although the term is misleading. We demonstrated not only simultaneous activation of antagonists and antagonists but also intermittent synchrony of individual discharges from opposing muscles, such as is found in peripheral nerve injuries during regeneration of axons. Disordered reciprocal innervation seems to be a more descriptive term for this type of dysfunction.

NEW ASPECTS OF MALARIA

LIEUTENANT COMMANDER DAVID R. TALBOT
(MC), USNR

On the return of millions of service men from tropical duty to civilian life at the end of the war it is going to become necessary for every physician to have a working knowledge of malaria and other tropical diseases. This knowledge must include certain new aspects of the nature of malaria and its treatment that have been brought out during this war. The fact that large groups of men have been under military control while being treated for malaria has made it possible to study this disease in an unusual way, by means of routine blood examinations, hospitalization and a more thorough follow-up of patients than would be possible in civilian life.

The material for a comparative study of two different theories of antimalarial tactics was furnished to me while I was doing duty as senior medical officer at an outlying military base, which for obvious reasons I cannot name, nor can I give the exact numbers of men included in these observations. The important fact is that two similar groups of men under identical conditions of living and exposure to malarial infection were handled according to two different accepted methods of malaria control. The one, the Army group, took atabrine (0.15 Gm twice daily) prophylactically on two days of each week, while the second, the Navy group, were being given treatment only as they showed symptoms or had blood smears positive for malaria. This region was one in which there had been a high incidence of malaria for a long time, and the obstacles here to the ordinary methods of malaria control were seemingly insurmountable. There were miles of adjacent swamp-land that could not be drained, and the dense jungle growth made it impossible to penetrate this area for oiling or other methods of preventing mosquito breeding.

There was also a large group of native people living adjacent to the military reservation, 95 per cent of whose blood smears revealed malarial infection. While effectual mosquito control measures were carried out on the actual base site, millions of mosquitoes came from the swamp areas and became infected with malarial parasites from the native population, then, in spite of bed nets and good screening, they infected our military personnel while the latter was engaged in necessary night duties. At this time it was decided to do routine blood smears on all of our personnel, regardless of presence or absence of symptoms of malaria. We made thick smears, using the Giemsa staining method in all cases. This method in the hands of trained personnel is time saving and according to Capt. Paul W. Wilson, U. S. Navy, it is thirty times as easy to find the parasite in a thick smear as in a thin one. It is also important to take smears on two successive days, as in *Plasmodium falciparum* infections no forms may be found loose in the blood stream on the day that the parasite is dividing. We were astonished to find that 66 per cent of the Navy personnel had malarial findings (35 per cent benign tertian and 65 per cent malignant tertian) while 48 per cent of the Army group likewise had positive findings (the malignant tertian also predominated in this group). Now, in the past there had been a rather high

⁹ Sanders, F. K. Repair of Large Gaps in Peripheral Nerves, *Brain* 65: 281-337 (Sept.) 1942.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the United States Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Department.

incidence of trunk easily diagnosed malaria in the Navy personnel while in the Army group the incidence had been quite low under a regimen of prophylactic treatment with atabrine but when the infection did occur in the Army it was much more severe and was slower to respond to treatment than the infection in the group that had not been receiving antimalarial prophylaxis. The only 2 persons who presented cerebral malaria with coma were in this group. The coma was the first symptom except for slight headaches in both. They were desperately ill men showing cyanosis, temperatures exceeding 104 F, rapid irregular pulse and rapid respiration along with their unconsciousness. Intravenous therapy was given these patients and fortunately both reacted favorably. This convinced us that the prophylactic treatment was masking symptoms while the infecting plasmodia were insidiously doing damage to the infected man's blood-forming organs so that when the malarial infection did break out the body's natural defensive mechanisms were so impaired that a more serious type of disease than usual resulted. We subsequently gave all Army men showing a positive slide intensive quinine treatment for four weeks. This routine kept almost all of this group from having clinical malaria. In the Navy men having positive malarial blood smears we instituted routine quinine and atabrine treatment. In most cases this prevented the development of clinical malaria but in an occasional one the quinine would have a provocative effect and precipitate an attack of chills and fever. We used plasmochin in an occasional case of resistant malaria on the theory then advocated that it destroys the sexual forms of the parasite which are ordinarily responsible for recurrences. However latest reports from Australia where plasmochin was much used refute this claim and although some feel that it has a use in the treatment of a case of stubborn infection showing repeated recurrences other authorities feel that it is so toxic that it should never be used. However, if it is used, signs of toxicity should be carefully watched for such as nausea, abdominal pain, cyanosis, methemoglobinuria, toxic nephritis with albumin, presence of red cells and casts in the urine, edema of the ankles and cardiac disturbances. If any of these symptoms appear to an appreciable extent, the drug therapy should be discontinued and the patient hospitalized. In spite of all treatment there will be some recurrences, especially of infection with *Plasmodium vivax*. We found an occasional case in which atabrine seemed to be ineffective against malaria. In these cases quinine had been given for a week in the treatment of an acute attack then atabrine had been given for as long as four or five days when the patient would develop high fever and chills, which would subside when quinine was administered again. There were also a few cases in which quinine likewise seemed ineffectual while atabrine yielded good results.

In comparing the action of these two drugs a few facts must be kept in mind. Quinine acts at once, due to quick absorption; atabrine acts slower due to slow absorption. Because of this it is sometimes recommended that atabrine 0.1 Gm. three times a day after meals for a week be given along with quinine 0.6 Gm. three times a day after meals for the first three days of treatment only or that atabrine be given as described for a week with the addition of 0.2 Gm. of atabrine intramuscularly twice on the first day of treatment thus getting a high concentration of atabrine in the blood at once. If there is nausea, stupor or coma, parenteral

medication is necessary. In this connection it is well to remember never to give atabrine intravenously or quinine subcutaneously.

Intramuscularly one gives atabrine dihydrochloride 0.2 Gm. or quinine dihydrochloride 0.6 to 1.0 Gm. in 5 to 10 cc. of isotonic solution of sodium chloride. In both instances the drug is to be given in alternate buttocks every eight hours until the patient can take medication by mouth. Intravenously one gives quinine dihydrochloride 0.3 Gm. to 0.6 Gm., taking thirty minutes to inject it in 100 to 200 cc. of water and repeats the dosage in eight hours if needed. This procedure should be reserved for very serious malarial infection as it may cause a fall in blood pressure, syncope or even death. Antidotes are caffeine and sodium benzoate, theophylline, ethylenediamine or methanamide.

Lumbar puncture and drainage are indicated when there is increased intracranial pressure as in cerebral malaria.

Of the 66 per cent of the Navy group with positive malarial findings the majority did not show any sign of acute illness. Some were men who had had malaria recently but had received inadequate treatment. Some had vague symptoms such as headaches, backaches and dizziness, this group being composed of those whose infection was in the incubation period about to develop as a clinical type of malaria. There remained a few who insisted that they felt perfectly well. Now I feel sure that out of this group if we had not given them treatment there would have developed a few of those atypical cases which often go undiagnosed because they are never characterized by chills or fever or any textbook course of malaria. Instead, the infection shows up with bizarre symptoms simulating like syphilis almost every known disease of the body. A study of these men with routine monthly blood smears together with a study of malarial patients in an outpatient department in which as many as 1,285 patients with malaria among the natives were treated in one month, convinced us that malaria was a much more complicated disease and had many more aspects than we had ever been taught to believe by the regular textbook portrayal of it. We especially had to give up the idea that chills and periodic fevers were constant symptoms of malaria.

To understand the symptoms better one should review briefly the pathology of malaria. Malaria causes destruction of red blood cells. There is selective localization of the parasites in the spleen, the liver and the bone marrow with cloudy swelling, fatty degeneration or even infarction and local necrosis resulting in these parts. There is in addition an invasion of the endothelial cells of the blood vascular system of any part of the body. Again localization of the malarial process may be due principally to the accumulation of large numbers of the parasites in the capillaries, these are sometimes referred to as embolic occlusions. The occlusions may lead to hemorrhage in a ring form and to destruction of adjacent cells and the tissues in the organs involved such as the brain, meninges, heart, gastrointestinal tract, kidneys, pancreas, thyroid, lungs and adrenals. It is held by some authorities that this later process occurs with *P. falciparum* only.

Malaria also frequently causes the occurrence of a positive Wassermann or Kahn reaction in percentages ranging as high as 80 (Taussig and Orgel). Other tropical diseases that have a like effect are yaws, leprosy, trypanosomiasis and relapsing fever. It is important to

remember that these reactions are not true antigen-antibody reactions (for syphilis) but rather that they result from the presence of a lipoidophilic substance which has the property of linking complement to the lipoidal antigen. If this is not kept in mind, grave mistakes will undoubtedly occur, wrongly influencing the diagnosis and treatment of malaria. In our experience the Kahn reaction would be positive frequently thirty days after blood smears of a treated patient were negative for malaria. We have no reliable information on just how long the positive Kahn reaction persists after the malaria is cured.

With these observations in mind it will be easy to understand why the following atypical cases of malaria could occur. Most of the patients with atypical malaria never gave a typical history of chills and fever. Yet every one of them had a blood smear positive for malaria and showed a favorable response to antimalarial drugs.

TWO GROUPS OF ATYPICAL CASES

1 In this group there were various manifestations of cerebral malaria. It simulated medical shock with its headache, fever and prostration, or sunstroke, heat exhaustion, acute alcoholism, acute mania or aschile psychoses. The symptoms cleared up or great improvement was noted on antimalarial therapy.

2 In this large group of cases the only complaint was of visual disorder with headache, often of long duration. Some of the patients had typical axial neuritis with clouding or dimness of vision, temporal or frontal headache and deep pain in the orbit which was made worse by pressure or movement. Under antimalarial treatment these patients usually improved, some with varying degrees of residual visual impairment. Some of the visual disorders were due to midbrain or cortical lesions from malaria.

3 Malaria may involve any other one of the cranial nerves, with appropriate symptoms. After the optic nerve the eighth nerve is the next in frequency of involvement with resulting vertigo and deafness. A pure malarial basilar meningitis is sometimes seen and might cause any of these lesions.

4 Damage to the thyroid or the adrenal gland from malaria may result in appropriate symptoms of various degrees of intensity. Replacement therapy with the indicated glandular products may be helpful in starting convalescence in these cases.

5 Embolic occlusions of malarial causation in the wall of the upper part of the bronchial tree may cause severe attacks of asthma or a persistent cough, usually non-productive, with negative findings in the chest on physical examination. These symptoms, which are often the only complaints, clear up quickly under antimalarial treatment.

6 Weakness, shortness of breath and a rapid pulse on exertion may be the only symptoms resulting from direct malarial cardiac damage, or there may be symptoms of damage to the vagus nerve.

7 Nausea and vomiting, especially in children, may be the only malarial symptom observed. This may be due to involvement of the central nervous system as in basilar meningitis, to pressure from an enlarged liver or spleen or to pancreatic involvement with deep seated pain.

8 Dysentery sometimes occurs as the first observed symptom. The patient with this complication of malaria shows intestinal mucosal capillaries filled with parasites. When this patient comes to autopsy the mucosa of the intestine is congested and dark red or

has a mottled appearance as in catarrhal dysentery, while the contents may contain mucus and blood cells, and the epithelial cells may be necrotic, with secondary bacterial invasion also showing in the mucosa.

9 The first complaint may be of urinary frequency, which is due to involvement of the wall of the bladder, or of discoloration of the urine red, brown or black. These symptoms accompany various degrees of renal alterations due to malaria, or the first complaint may be of anuria, as in acute malarial nephritis or the terminal stage of blackwater fever.

10 Bilhary malaria is first evidenced by slight jaundice, and the patient may show a remittent type of fever. This was a fairly frequent form in our experience and responded somewhat slower to quinine than other forms.

11 Pronounced pallor of the face with a bluish or yellowish tinge to the scleras may be the only evidence of malarial infection in persons who insist that they feel fine and are perfectly well but just have the "tropical pallor," though a thick smear shows numerous plasmodia in their red blood cells, as well as definite anemia.

12 There remains one group of cases which are put together only because of the common factor of inconsequential symptoms—cases in which vague neuralgia or pains in the muscles or joints or various untypical cutaneous eruptions occur as the only symptom, blood smears are positive and recovery occurs on quinine therapy.

This enumeration of groups of atypical cases of malaria is not complete, but it points out that the patient who has lived in a district where malaria is endemic should be considered as having malaria until this diagnosis is disproved.

CONCLUSIONS

1 In areas of endemic malaria it should be a monthly routine to examine thick smears of blood from all military personnel, two specimens being taken on successive days. All persons with smears containing malarial parasites, even those without symptoms, should be treated vigorously to forestall attacks.

2 In general, the policy of treating men for malaria only after they become infected is better than prophylactic treatment if adequate laboratory facilities are available. Certainly this rule holds in peacetime or at any base where military urgency does not require that a maximum number of men be kept in the field to fight. However, in an area of active combat especially where malaria caused by *P. falciparum* is endemic, prophylactic antimalarial measures must be adopted.

3 Treatment of malaria with both quinine and atabrine (when both are available) is more effective in preventing recurrences than prolonged treatment with one of them. Plasmochin may be indicated in rare, specially selected cases of repeated occurrences.

4 As the result of some idiosyncrasy, an occasional person will be found whose malarial infection does not respond to atabrine or, again, to quinine. The treatment will then have to be given with the single effective drug.

5 The diagnosis and treatment of malaria will be wrongly influenced if a positive Wassermann or Kahn reaction is considered pathognomonic for syphilis.

6 Malaria, like syphilis, may simulate different diseases of every part of the body, and the absence of chills and fever should not rule out its occurrence in people who are living or have sometime in the past lived in the tropics or other areas of endemic malaria.

CONTACT, CONTACT-INFECTIVE AND
INFECTIVE-ALLERGIC DERMATITIS
OF THE HANDSWITH SPECIAL REFERENCE TO RUBBER GLOVE
DERMATITIS

JOHN H. STOKES, M.D.

WALTER E. LEE, M.D.

PHILADELPHIA

AND

HAROLD M. JOHNSON, M.D.

HONOLULU, T. H.

This somewhat cumbersome title covers the substance of a lecture to Army surgeons on infections of the hands (and feet) currently being given by one of us (J. H. S.) with the tribular analytic summaries for mnemonic purposes which accompany it. The presentation is based on material which aggregated 200 cases in the senior author's practice ten years ago and has grown recently out of all bounds in the direction of the physician's (and surgeon's) hand. Since as Ecclesiasticus has well put it, for surgeons "the handiwork of their craft is their prayer," and since the same authority has said that in the physician's hands is the issue of life, it appears worth while to offer a critical analysis. Such a method of analysis is, in our experience useful in industrial medical practice, now a major defense problem, as well as in the field, the household and the medical office and surgical clinic. Application of the principles tends to render refractory cases amenable, reduces the severity of initial and relapsing infections, may restore incapacitated persons to usefulness and may make surgical treatment for deep or extending infections unnecessary.

The scheduled title of this lecture, 'Dermatophytosis', well illustrates the first problem—to get the medical man over the idea that a single causal agent and a fungus acting alone at that, accounts for all or most dermatitic and especially vesicular and vesicopustular eruptions of the hands and feet. Having endured the blistering scorn of internists at our hesitancy in calling foot rashes, especially interdigital ones "dermatophytosis" when to the medically experienced [sic] eye they are obviously "athlete's foot," we have become dogged in our insistence that the mycotic be invoked only when pathogenic fungi are demonstrable. All other rashes, hand or foot, and in fact the fungous ones too, are compound affairs, susceptible of being designated after adequate study by such titles as mycotic-pyogenic, mycotic or pyogenic-allergic (or both), contact-allergic or contact-infection-(mycotic or pyogenic) allergic lesions—the terminology being analytically expandable, like that of organic chemicals, to almost astronomical hyphenization and syllabicization (to coin still another word). The infecting organism or the exciting (perhaps contact) cause is the trigger puller for an often well camouflaged but heavily loaded gun, the patient himself, loaded with predisposing (and other exciting) causes. To tamper with the trigger even by a patch test may lead to the usual effects or overlooking the (loaded) gun. The background of a contact or infective dermatitis of hand or foot, while not so immediately important as the foreground may contain the explanations unattended to, for chronicity, relapse, uncontrollable extension and noncure.

Table 1 emphasizes the two groups of causes which should be looked for in any painstaking study of a case. Running comment is offered as follows. The family history will usually expose evidence of general allergic tendency, which will usually be emphasized (though not always) in the patient. This does not mean at once alone. Susceptibility to pyogenic and to much less degree to fungous infection also runs in families and sticks out in many of these personal histories like a sore thumb (acute ears mastoids osteomyelitis styes boils impetigo acne and so on). The interplay of infection and allergy must always be kept in mind—a severe infection and a virus infection especially tends to 'broaden the allergic base'—increase the range and seriousness of contact ingested and inhalant allergy (i.e. sensitizes the individual). This is repeatedly observed in the flares of hands following sinus infections and of course in the development of wholly new contact and other sensitivity occupational and otherwise following focal and intercurrent infection. In many cases with allergic backgrounds one witnesses the sudden extension of eruptive manifestations, locally or over the body generally or to special regions (the ears and center face the flexures especially axillary and antecubital). These extensions are spoken of dermatologically as 'ids' (phytids mycotids bacterids, pyids) as an expression of the extending broadening or heightening allergic susceptibility of the individual to his infecting agent. In fact paradoxically, some eruptions on the hands begin on the feet and, because the organisms have been difficult or impossible to find, have been designated as allergic secondaries" or "ids. Better methods are tending especially in pyogenic allergic cases to show that organisms, usually hemolytic staphylococci or streptococci are present in the numerous pustules of these 'ids' though by original definition an 'id' was supposed to be a toxic affair the organisms absent. One must constantly think then in eruptions of the hands of infection allergy as well as of general and can act allergy and their concomitants and consequences local and systemic.

The ichthyotic and seborrheic constitutional trends in skin behavior varying with heredity and with such elements as age and diet, are critically important. The parchment palmed horny kneed and elbowed person cannot use soap. Alkali prepares him for local allergic reaction. The seborrheic cannot guzzle sweets. The explosive extensive 'ids' are commoner perhaps in the seborrheic the refractory localized (contact) eruptions in the ichthyotic. Constitutional trend underlies a large group of industrial and professional skin difficulties of infective contact-infective, contact-allergic, infective and infection-allergic types.

Items 7 and 8 under 'Predisposing Causes' represent newer conceptions of skin physiology of importance in the behavior of infections. The hands and feet are played on incessantly even in normal persons by vasomotor and sweat impulses—they blush and pale are moist and dry influenced by thought emotion posture and activity—and these effects are exaggerated in the abnormal to produce the red hot or the blue cold the dry or the clammy extremity with its changes in blood borne pabulum pH reducing body content of sweat and outright vascular stasis and interstitial edema. If one is looking for offhand illustrative material for this lecture let him call forward from the audience the pink eared moist and red handed members. The skin

hydration mechanism has an unfamiliar literature and much to investigate, but we are impressed with its importance and the usefulness of dehydrative devices in treatment. Especially is it worth while to stress, as the cause of many failures, subthreshold local edema of foot and leg, associated with "blue foot" and with mild cases of varicosity, recognizable only as the patient compresses the return circulation by sitting with the legs dependent over a sharp edge such as a chair or a table. In such cases compression bandaging for a time, and in some cases a light elastic stocking, often do away with the persistence or relapsing tendency of the foot and ankle eruptions. Contrast bathing (hot-cold) is often helpful too, and incidental and occasional elevation, which may even aggregate several hours a day (feet on desk). Of the remaining predisposing causes, heat and

tion that staphylococci like it too (carbohydrate-like) and it does flood the skin with blood (vasodilatation and congestion).

Passing now to the exciting causes, on clinical grounds we believe that the original mycotic invader in some of these hands and feet simply prepares the way, as in the Ravaut-Rabeau conceptions of inguinal (flexural) streptomyces, and is soon lost sight of in a burst of symptoms due to a secondarily invading pyogen. This may be a streptococcus producing lymphangitis and lymphadenitis, fever and so on and erysipelas-like extension of the original lesion. Far more often, however, in our American experience it is a hemolytic staphylococcus, recoverable by both aerobic and anaerobic methods, more abundantly sometimes by the latter. We accept the pathogenicity of this hemolytic staphylo-

TABLE 1—Causal Analysis, Skin Infections (Dermatitis) of the Hands and Feet (Mycotic, Mycotic-Pyogenic, Mycotic-Pyogenic-Allergic Dermatitis)

PREDISPOSING CAUSES	EXCITING CAUSES (Original and Flares)
1 Allergic family background	1 Inoculation and reinoculation with infective agent (a) Fungus and pyogen relationships (b) Environmental and contact exposure
2 Innate infection susceptibility (allergy of infection?) especially pyogenic	2 Development of (a) local or (b) general allergy of infection (phytids and bacterids)
3 Personal allergy and pyogen susceptibility Allergy and infection interrelations "Broadening the base"	3 Ingestion of an allergen (food)
4 The ichthyotic or dry skin habitus Predisposed by use of soap and other alkali contacts, because of lack of fat (oil) defense	4 Ingestion of a drug (barbiturates)
5 The seborrheic or oily skin habitus Predisposed by fat gland over activity and congestion to phytids and bacterids, and to both fungous and pyogenic infections direct	5 Common contacts (contact allergens) (a) Alkali sensitiveness—soap, etc (especially in ichthyosis) (b) Rubber—gloves, occupational contacts with chemical catalyzers, etc (c) Leathers and glove and shoe processing materials (d) Medicaments and medical contacts, procaine etc disinfectants, dusting powders, etc (e) Wool (f) House and occupational dusts, oils, cleansers, etc (g) Plants (oleorinsins, etc) (h) Miscellaneous chemicals (i) Physical agents—light, heat
6 Vasomotor and sweat mechanism, functional disturbances (a) Hyperhidrosis (b) Red or blue cold hands—"neurocirculatory instability" (Becker) (c) pH and reducing body content of sweat (d) Contact of skin surfaces Effect on concentration of oxygen, etc	6 Emotional shock and crisis
7 Causes of skin hydration (a) High carbohydrate intake (b) Alcohol intake (c) High alkaline ash food intake, especially fruits (d) Causes of edema (1) Varicosities and peripheral stasis (small amount) (2) Serum protein globulin reversal (3) Heart and kidney disease (e) Diabetes	7 Intercurrent infections Especially virus infections of nasorespiratory and gastrointestinal tracts (sinuses, etc, mild, subthreshold infectious, time of onset duration?)
8 Causes of vasodilatation (a) Heat and humidity (b) Motion (c) Histamine (d) Fatigue (e) Allergens (f) Alcohol	
9 Causes of vasoconstriction (a) Arterial disease (b) Vascular spasm	
10 Causes of sweating (a) Nervous, emotional tension (b) Atmospheric conditions—heat, humidity (c) Impervious clothing, including shoes and gloves	

humidity are the gift of the weather, though sometimes of clothing and occupation.

Emotion expresses itself on the hands in much the same way that the rosacea complex is expressed by the flush area of the face. It is fascinating to watch the color play from relative pallor to lividity of the dermatitic hand, prepared by overwork, strain and fatigue and to see the itch begin and the scratch follow, with wringings and twistings, as the patient, all unconscious of what his members are doing, unburdens his mind and heart with bitten lip and suffused eye. "The hand cries for you" we say—and in none more bitterly than the poker faced but harried physician and the driven surgeon. Histamine bodies we mention with hesitation as theory to explain vasodilatational effects with hypotension and carbohydrate intolerance possibly due to absorption of histamine bodies from the intestinal tract (Kendall syndrome). Alcohol we mention too with hesitation because we respect what contributes to conviviality these days—but we cannot escape the convic-

coccus and would point out that it is present in the most varied types of acute, subacute and chronic dermatitis without necessarily any conventional "impetiginous" characteristics. The clinical earmark is the milium pustule usually at the periphery of a young lesion, often only just seeable with a 3 to 5 diameter lens. If the patient has become allergic to this organism he may sustain extensive "id"-like outbreaks involving elbow flexures, axillas, face, ears, with fever and more rarely lymphangitis. The last trace of fungus, if ever present, has vanished in the melee, so far as scrapings and culture show.

Across the mild or severe allergy of infection presented by these patients play the other allergens of their allergic pattern. Bacon explodes a urologist. Coffee as an allergen overlooked for years leads when removed after identification to a 75 per cent reduction in symptoms. House dust is a common offender in women (dishwater in France). Soap as an alkaliizer prepares the skin for contact allergens of all sorts. Light

sensitiveness follows a bout of intestinal 'flu' (coproporphyrin absorption) and on the trauma inflicted by the allergen appears the hemolytic staphylococcus. This does not mean that all contact irritation transforms itself forthwith into infection and infection allergy but it should be looked for. Twenty minutes of the wrong rubber glove may mean three to six weeks in bed.

Environmental exposure for physicians may include outbursts following the opening of a boil or abscess with unprotected hands quite as much as stepping on a dirty bath mat or locker room floor with unprotected feet. Our observations on the effect of barbiturates (item 4) are based largely on the homology of the bullous type of this drug eruption to the acute infective dermatitic hand. Many physicians with bad hands have been fighting tension with sedatives of this type, but the frequency may be merely coincidental.

The contact factors name may of course be legion. Only the commoner groups of contact allergens are named in table 1. The case histories later presented are those of physicians and emphasize the rubber glove, and particularly the so-called latex glove as the trigger. Suture tube fluids local anesthetics of the 'caine' types are frequent offenders. The morphology of the glove eruption finally arouses suspicion though it may be years before the conviction dawns on the victim—a dusky, often livid and 'burned' look to the dermatitis most apparent on the back of the hand with a cuff encircling the wrist, almost suggestive of pellagra or photodermatitis. At first irritation may be slight and cumulative, but as the allergic response is stepped up the itching begins in fifteen minutes the dermatitic disability may last for six weeks following a single contact (case 3) (background causes) and may be immediately converted into a violent hemolytic staphylococcus or streptococcus infection without preliminaries that can be recognized. Rubber is of course, a chemical goulash of synthetics, gum accelerators vulcanizers, antioxidants, any one of which or several may be allergens or become such for susceptible (backgrounded) persons. The composition of rubber changes constantly with new discoveries the ingredients are often secret, extremely minute amounts may be profoundly allergenic or irritant. There is a story that one handbarrow load of old shoe heels containing hexamethylene, added to a batch of new materials, brought down the staff of a plant with a dermatitis. Certainly one pair of gloves worn for one operation can do it for the surgeon who is susceptible.

When a contact dermatitis is suspected, patch test search of all possible ingredients may be resorted to, though close questioning and the distribution of the dermatitis provide good clues. Patch tests especially to high concentrations of the types of substances named may produce violent local reaction at the test site and even extensive 'id' manifestations so that patch testing with them is not without risk. When the surgeon begins to suspect his gloves he should try wearing a very thin silk or cotton glove under the rubber one. If this brings pronounced relief American Anode Inc., Akron, Ohio will supply a patch test kit and will moreover, make gloves to order excluding therefrom the incriminated agent. A dermatologist or allergist should do the testing. A piece of the offending glove should also be used. When the glove is definitely incriminated one or other of two (relatively) non-

allergic types may be tried—Neoprene gloves made from the du Pont synthetic by the Pioneer Rubber Company Willard Ohio or the dark glove made by the Seamless Rubber Company, New Haven Conn. Every person responsible for gloves on the operating and supply room staff should be put on the alert for a single mistake may cause a sensitive surgeon prolonged discomfort and incapacity. Thus far no satisfactory method for desensitization to these highly toxic substances has been worked out and avoidance with correction of the background is the only resource.

Of other contact excitants mentioned wool brings in a good many women's hands these days through Red Cross knitting activities. The sensitiveness may be interred by flares after avoidance, but wool is so general a contact in clothing that it is best tested for specifically by patch with the ether and alcohol soluble extracts. Leather, like rubber, is a goulash of processing materials and shoes must be dissected and glove linings examined and the patch materials must be applied so as to test both sides, to detect reactions to glaze, glue and rubber cement. We recall one young patient whose feet finally recovered when she was provided with rubber cementless shoes and her hands when she stopped turning handsprings under the lilac bushes (proved allergy to lilac).

The importance of soap in hand dermatitis concerns both its alkalinizing qualities and its content of specific allergens. Of the two, the former is the more important. The action is a double or treble one including removal of the oil or fat defense by emulsification elevation of the surface p_H thus attacking the defensive 'acid mantle,' and the creation as Burckhardt has shown of a local allergen susceptibility. The influence of alkalization varies from person to person some individuals being apparently constitutionally deficient in skin alkali neutralizing capacity. Because of this complex of considerations the avoidance of soap and of alkali in housework and industrial processes is often of critical importance in preventing eruptions of the hands, and nothing can be accomplished if the patient will not accept the use of a detergent cream containing a wetting agent for cleansing, and use it invariably, not just occasionally. If defatting (as in ichthyotic or xerodermic persons) is the principal trouble some tolerance of soap can be secured if the hands are insistently and persistently and repeatedly inuncted between washings with a bland nonperturbed grease (simple lick-and-a-promise rubbing won't do) to which the patient must not be sensitive (cholesterinized petrolatum is effective). Rubbing in such a grease just before washing as the industries have found or even before beginning dirty work helps. Even the draining of soapy water over the feet in a shower affects some persons unfavorably and the spigot-heel-suspension posture in the bath tub must be adopted.

Light sensitiveness is rarely if ever an affair of the hands alone but in extensive 'id' cases especially with involvement of the face it must be suspected. It develops in patients who concomitantly may have a coproporphyrinemia the apparent source of which is a porphyrin-producing stool flora. Just what starts this flora in the intestine is not known but we have seen light sensitiveness of the hands follow virus infections (nasorespiratory and gastrointestinal) and suspected that their apparent ability to excite it depends on their paving of the way for other pathogens. Improvement

can be brought about by hastening the elimination of the circulating porphyrins with oral administration of nicotinamide

The influence of nasorespiratory infections on hemolytic staphylococcus infections of hands is recognizable by patients as well as ourselves. It is apparently an induction of infection allergy to judge by the provocation of extensive "rids" in some cases and "allergy" to the staphylococcus rather than the viruses. Apparently the sensitization interval is from eight to thirteen

drug rash may be diagnosed. It is in these cases that we suspect the barbiturates with which the patient or physician is crutching himself to be contributory, by a Milian type of provocative reaction.

TREATMENT OF HAND AND FOOT DERMATITIS

While some cases of hand or foot dermatitis are refractory and even incurable, most persons not already burned by x-rays, or hampered by the accumulated irreversible pathogenic processes of later life, make

TABLE 2—Directions for the Patient, Causes and Prevention of and Treatment Directions for Ringworm or Fungous Infections of Hands, Feet and Groins

- 1 So called "ringworm," "athlete's foot," "prym itch," etc., is due to a fungus or microscopie plant, midway between a yeast and a mold very tough and hard to kill.
- 2 Other terms may take advantage of the situation and complicate a fungous infection with serious effects.
- 3 No one who knows what he is about promises to "cure" permanently fungous infections of the feet. They can be cured or improved but the elements of susceptibility and reinfection make it impossible to say whether or not and how soon any given case may be cured.
- 4 Your cooperation is as important as our treatment—more important in the long run. You must keep yourself well.
- 5 The infection is rarely dangerous but it may be, especially in later life and in sensitive persons. It comes and goes, has ups and downs in the same person is helped by a vast number of remedies.
- 6 The infection is made worse, among other things, by
 - (a) Moisture, sweating, heat (hot weather and exercise, hot sand, hot impervious or sweaty shoes, wool socks, carelessness in drying the feet, especially between the toes).
 - (b) A diet very high in starch and sugar (sweets including fruit juices, ice cream and soft drinks).
 - (c) The use of alcoholic beverages.
 - (d) Nervous tension, stress and strain, from any cause, including fatigue and nervous overwork.
 - (e) A special susceptibility or sensitiveness to the germ (allergy) in certain people.
- 7 The common sources of infection are
 - (a) Moist surfaces used by many bare feet—bath mats and floors, showers, swimming pools and gymnasiums, bath houses, toilet seats.
 - (b) Walking barefooted anywhere.
 - (c) Your own wool and silk socks, old slippers and shoes.
 - (d) More rarely, other people's bodices and clothes.
- 8 Apart from the precaution of not walking barefoot or exchanging towels, clothes, footwear, there is little likelihood of passing on the disease. All susceptibles get it from the aforementioned sources (7).
- 9 The general principles of control and prevention are
 - (a) Break yourself completely of the barefoot habit. Never touch a bare foot to the floor, carpet or mat.
 - (b) Dry and cleanse your feet completely every day, removing all scale and moisture, especially between the toes. Do not overuse soap.
 - (c) Use cheap straw, paper or wooden clog slippers and burn frequently.
 - (d) Wear cotton socks and boil them after each day's wear when infection is active. Avoid wool socks at all times.
 - (e) Avoid sweaty shoes and hot footwork.
 - (f) Exchange no clothing with any one.
 - (g) Never scratch, rub, pick, pull or tear. If instructed use scissors, sandpaper, towel and toilet paper.
 - (h) Do not use iodine without medical order.
- 10 To prepare purple solution (potassium permanganate)
 - (a) Remember the solution must be made fresh each time. If it turns brown or muddy while in use, mix some fresh.
 - (b) Potassium permanganate requires a prescription. Use the number of tablets per quart of warm water called for by the prescription. If using crystals, make the solution the color of beet water so that you can still see a mark on the bottom of the dish.
 - (c) The solution stains finger and toe nails brown but the color can be removed with lemon juice or oxalic acid (poison!). Basins and tubs can be cleansed with cleanser. Acid spoils the enamel.
 - (d) In soaking hands or feet, use an enamel basin deep enough to immerse to ankle or wrist. Save time by standing in the basin while shaving. Soak for — minutes (usually 10-20).
 - (e) For baths, use 3 tablespoons of a saturated solution to the tubful of warm water. Clean tub at once after use.
 - (f) After soak, rub the surface clean with old cloths or, better, paper towels or toilet paper wads. Rub off all the brown and dead skin possible.
 - (g) For sponging surfaces, use gauze or a cotton and a rubber glove on hand.
- 11 Clipping and scraping directions
 - (a) Thoroughness determines success or failure at the start. Later it can be overdone, but few do it.
 - (b) Use the blunt end of a new steel nail file, held vertically as a scraper. Do not tear or pull.
 - (c) On dry scaling or thickened surfaces (not between toes), use emery boards (as purchased for finger nails) or 00 (double 0) sandpaper in 2 inch squares (hardware store). Do not grind to the point of soreness, bleeding or oozing. Use fresh sand paper frequently.
 - (d) Chip blisters with sharp manicure scissors used for no other purpose. Soak in alcohol before and after use. Stick one point into the blister top, clip and slit. Then insert the blade at one end of the slit, cut a second, turn back the V shaped flap and cut it off at the base. Have us show you. Be conscientious. Open all small blisters this way.
 - (e) Apply paints directly to the skin. Ointments spread on gauze. Keep ointment soaked gauze between sore and sticky toes.
- 12 In acute cases, keep off the feet. Sit with them elevated to a desk top or chair whenever possible.
- 13 Remove constricting articles of clothing such as garters and rolled stockings.
- 14 If using supporting bandages note the following
 - (a) Change and wash elastic bandages every other day as directed with package.
 - (b) With roll uppermost (away from skin) start with end on top of foot just behind toes, roll smoothly with firm pressure (not too tight), overlapping each turn one half. Toes should not swell or prickle.
 - (c) Cover the heel (demonstration).
 - (d) Run bandage up to just below the knee.
 - (e) Remove bandage after going to bed. Put it on before rising.
 - (f) Replace bandages that have lost their elasticity (at least every 30 days).
- 15 If you feel an attack coming soak feet 20 minutes in purple solution ice cold in summer, hot in winter
 - (a) Use the salicylic alcohol solution as directed.
 - (b) Dust the powder between the toes 2-3 times a week.
 - (c) Try a little ointment from your stock, preferably the yellow one.
 - (d) Open the stray blisters as you have been taught.
 - (e) Watch the skin between the 3d and 4th and 4th and 5th toes especially and keep after it.
 - (f) Carry out orders regarding diet, alcohol and nervous influence.
 - (g) Don't be easily discouraged or alarmed. Try these directions first, then get medical advice before the relapse is complete if you can't control it.
- 16 If you can interest a school board or club in preventing infection with athlete's foot and care to do so, ask for further information.

days, but since patients may become subthreshold clinical cases before symptoms appear, the general symptoms may become outspoken only about the time the skin flare begins. A spreading erythema, increased edema, a shower of pustules locally, extension without change in morphology, local lymphangitis and lymphadenitis, sudden involvement of the predisposed flush areas (ears, center face), flexures (intertrigo) or a wholesale outbreak of a follicular papular, patchy or diffusely confluent dermatitis, each or severally, constitutes the flare. A truly magnificent outburst of pustules from head to foot or a pemphigoid bullous eruption with fever have more recently marked the extreme grades of sensitization and require oral sulfonamide therapy. A

gradual recoveries. Failures are usually due either to (a) a one-track view of the case, diagnostically or therapeutically, (b) nonadherence by the patient to a tedious and exacting regimen or (3) nonattention by physician or patient to detail. Since the last mentioned involves instruction which, we have learned, must be full and specific, the minimal directions and information given the patient in the senior author's office are here reproduced (table 2).

Table 3 arranges treatment under the three categories suggested by the analysis of causes. In military life, especially of Americans in the tropics, and among workers in the industries, much trouble can be avoided if selection of personnel can be exercised.

How can a surgeon prevent rubber glove dermatitis? First by not becoming a surgeon if he classifies in column 1 class 1. Second by heeding the instructions for the care of his feet. Third by staying within bounds and the more so the older he becomes on alcohol carbohydrates sedation rest and work. Fourth by knowing what he uses and what he wears on his hands (and feet) and sticking to the least sensitizing and least irritating for him. Fifth the allergically backgrounded individual should have his allergic pattern studied as early as possible and again after severe infections which broaden his base. And finally as any good surgeon does he should avoid infections and infective material and not expose his bare hands to

Passing to the systemic therapy, the opening dose of hydrochloric acid requires no test meal if no history exists suggesting hyperchlorhydria or ulcer. The older the patient and the more flushed the face (rosacea complex) the larger the indicated dose (20 to 60 minims [1.25 to 3.7 cc] three times a day) may be. Glutamic acid hydrochloride (one capsule equivalent to 10 minims [0.6 cc] of diluted hydrochloric acid) is a very acceptable substitute for the bottle-dropper-tube nuisance. It is necessary to watch the weight and fatigability in reducing the intake of carbohydrate by younger persons and fruit and juice guzzling as a source of carbohydrate as well as alkaline ash food in general must be checked.

pyogens or his feet to fungi. Dashing wielders of the pocket bistoury, and inveterate golfers, take heed.

In the prophylaxis of foot infection, important for protection of the hands, item 2 in the preventive column should be made a lifelong habit, item 3 is prevention, not treatment, item 4 permits sterilization by boiling (change every day, boil, wash, rinse thoroughly), certain shoes provoke infections possibly by allergenic content or provoking perspiration or preventing evaporation. Item 6 is much overdone by most patients who soak and wash unnecessarily with soap under the mistaken impression (odor) that dirt and putrefaction are at the bottom of their troubles. In item 7 manual clean-up can be done with paper towels or toilet paper wound around the finger and "reamed" between the toes. In item 8,unction of a grease is ineffectual without time (three to five minutes) and detail (between and under the toes).

Rest and psychotherapy, though treated by single words in the outline, are basic inescapable essentials. One of the most important medicaments in the hand-foot armamentarium is DGAD—not digitalis, gonadotropes, aspirin and diaphoresis (of copper) but huge doses of Don't-Give-a-Damn the psychologic soporific that reduces the eternal friction between what one feels he must do and what one thinks he can. As a guide to the finding and taking of this now increasingly scarce preparation a four page written prescription impossible to reproduce here is handed out to the patient in the senior author's office and then hammered in by one to three or more talks on principles of living which it must be admitted are too deep or fix too high for many physicians and surgeons to grasp or apply them. They see the point but the nub of the matter—to do something about their own tension-mindedness, their own overwork, their own disposition to violate rule 5.

Seventeen days later a violent flare occurred with acute lymphangitis, fever and a leukocytosis of 16,000. He was hospitalized.

Special studies were undertaken. Bacteriologic examination disclosed hemolytic streptococci and staphylococci. Oral sulfanilamide and sulfapyridine therapy resulted in much improvement but considerable residual dermatitis. Focal infections consisted in an opaque sinus and mucocle (?). With regard to allergy, ingestsants included a number of weak positives including several food favorites but not including perches which had been shown to be responsible for hand urticaria. Contactants included dog fur (he has three dogs),orris root (he cannot use scented powders) and wool. Experiments with a therapeutic lamp (Si) indicated that he was from time to time or had become transiently light sensitive. Staphylococcus toxoid tests and tests to an autogenous hemolytic streptococcus suspension indicated by necrotizing reactions with lymphangitis, a hyperallergic reaction to his infecting organism. The flare effect ("broadening the base") of virus infection even in members of his family (recall his allergic type sinus involvement) was several times demonstrated.

Rubber gloves were finally suspected to be the excitant, although at first the possibility was specifically denied by the patient, following relapse after a long operation in which practically well hands began to show irritation in twenty minutes (dark rubber gloves). A patch test from these gloves was positive. Neoprene gloves were tolerated, but a standard rubber glove a year later provoked a relapse after thirty-six hours despite the fact that a cotton glove had been worn under the rubber glove. Seven three years later the patient, employing allergen eliminative precautions and wearing nonallergic gloves, had reduced his dermatitis to faint traces on two finger webs, and he was able with the usual washing technic to carry a full operative schedule. His background had been materially improved. Lasting desensitization had not been accomplished.

CASE 3—An industrial physician aged 55, heavily overworked by the war emergency, developed in 1940 a dermatitis involving the tips, dorsa and sides of the fingers. The hands were equally involved from the start, a puzzling factor until it was found that he was truly ambidextrous. The distribution to contact points likely to be involved in his dispensary work suggested procaine hydrochloride, pontocaine hydrochloride, suture ampule fluids and alcohol denaturants as leading excitants, acting on a soap predisposed (low skin alkali tolerance) background. The fingernails suggested mercury bichloride effects, the toenails fungous infection, scrapings overlooked.

As predisposing causes, his children had mastoiditis, suppurative appendicitis, infantile eczema and hay fever, patient himself lobar pneumonia, catarrhal jaundice, severe tonsillitis, quinsy, mild appendicitis, athlete's foot, and influenza in 1918. His diet had a high sugar content and he was a moderate user of alcohol. He did not use drugs. The tonsils were infected. Infected teeth were removed without benefit. There was an old sinusitis. His nervous load included family problems, responsibility for 16,000 men, inadequate assistance and private practice. He was troubled with sweating hands (rubber gloves made his condition worse).

As exciting causes, contacts included dog fur, Lifebuoy soap (which caused itching), ST 37, Kaldernic suture fluid, catgut and suture fluid (xylene?), pontocaine hydrochloride and procaine hydrochloride. From the distribution, pontocaine and suture fluid were suspected. Latex rubber gloves were routinely tested. Positive patch tests were obtained to both suture fluids and pontocaine. Procaine was negative.

The latex glove test was mildly positive after twenty minutes' exposure of a patched site.

Almost complete recovery followed a nonsoaping and greasing regimen with protection from allergens by nonallergic rubber gloves. This was in contrast to the previous elaborate but unsuccessful treatment, including x-rays. Slight fissuring persisted at the finger tips. The evaluation was incomplete because (a) search for a fungus was not made and (b) a general allergic workup was not done. Another infected tooth was found, infected tonsils were not removed and the prostate was not studied. Improvement was 85 per cent.

Clinical Notes, Suggestions and New Instruments

A NEW TEST FOR THE DETECTION AND THE APPRAISAL OF EXPOSURE TO TRINITROTOLUENE

R. K. SNYDER, PH.D., AND W. F. VON OETTINGEN, M.D., PH.D.,
BETHESDA, MD.

In the course of an experimental study of the toxicity of trinitrotoluene and the mechanism of its action, it was found that trinitrotoluene is partly reduced in the organism with the formation of amines. One of these is presumably 2,6-dinitro-4-aminotoluene. Although sufficient quantities for chemical identification have not been isolated from the urine so far, certain characteristics seem to favor this assumption. It appears very likely that other reduction products such as mononitrodiaminotoluene and dinitrohydroxylaminotoluene and its derivatives may be encountered, but so far none of these have been identified by us in urines of experimental animals and man. These studies are still in progress and will be reported at a later date together with a discussion of the pertinent literature, but a test developed for the determination of 2,6-dinitro-4-aminotoluene was applied to a large number of urines of workers exposed to trinitrotoluene and was found to be more sensitive and more quantitative than the Webster test or any of its modifications. In a study of 98 women and 245 men exposed to trinitrotoluene the average daily excretion of the amine was found to be 129 mg and 206 mg, respectively, with 0.0 and 33.5 and 0.27 and 28.75 mg as extremes. For this reason the original method was simplified and adapted for clinical use so that it might be used for the appraisal of exposure of workmen handling trinitrotoluene. This method is based on the extraction of the metabolites of trinitrotoluene with ether and determination of the amine in the ether extract after evaporation of the ether by diazotization and coupling with α -naphthylamine, extraction of the latter with toluene, and comparison of the orange-yellow color formed with a set of standards.

The procedure is as follows. Place 50 cc of urine in a 125 cc Erlenmeyer flask, add 2 cc of hydrochloric acid (specific gravity 1.18) and boil gently for one minute. After cooling, add 1 drop of capryl alcohol and 3 to 4 Gm of sodium bicarbonate in divided portions. After the evolution of carbon dioxide has ceased, shake the solution thoroughly but not vigorously with 100 cc of ether in a separatory funnel for five minutes. Allow the layers to separate and wash the ether layer successively with 25 cc of 1 per cent sodium carbonate solution and 25 cc of distilled water. During this extraction, emulsions occur frequently. When this happens allow the mixture to stand until the layers are reasonably well separated, drain off the lower layer and proceed with the washing. If the emulsion persists, add, after the last washing has been drained off, sufficient anhydrous sodium sulfate to break the emulsion in the ether layer, allowing the clear ether layer to be decanted. Using aliquot portions of the ether extract, the ether is evaporated or distilled off from a 125 cc Erlenmeyer flask containing 10 cc of water acidulated with 3 to 4 drops of 2-normal hydrochloric acid. Transfer the aqueous residue while still hot to a 25 cc glass stoppered cylinder, cool to 20 to 25 C and add in rapid succession, with adequate agitation after each addition, 1 cc of a freshly prepared 0.1 per cent solution of sodium nitrite, 1 cc of 0.5 per cent sulfamic acid and 1 cc of a freshly prepared saturated aqueous solution of α -naphthylamine. Let the mixture stand for about ten minutes, then add 10 cc of toluene and shake vigorously. Separate the layers and transfer the toluene extract to a test tube of the same size as used for the preparation of the standards, add about 1 Gm of anhydrous sodium sulfate, shake, and compare the intensity of the color with the set of color standards.

The standards are prepared as follows. 1 Gm of chemically pure methyl orange is dissolved in 100 cc of distilled water and 14 cc of this solution is diluted to 100 cc with

in distilled water. 2 A buffer solution (No 1) is made by adding 0.40 cc of fifth molar sodium hydroxide to 50 cc of fifth molar potassium acid phthalate and diluting to 200 cc with distilled water. 3 A buffer solution (No 2) is made by adding 3.65 cc of fifth molar sodium hydroxide to 50 cc of fifth molar potassium acid phthalate and diluting to 200 cc with distilled water. For the preparation of the standards the proper amounts of the methyl orange solution and the buffer solutions are mixed as given in table 1 to make 10 cc in clean Pyrex test tubes, which are then sealed. If kept in the dark when not in use these standards will not change color for at least three months.

Since the range of these standards is limited to concentrations of 0.01 mg to 0.15 mg of 2,6-dinitro-4-aminotoluene per 10 cc, it may be necessary in some cases to use aliquot portions of the original ether extract of the urine for the determination. With low concentrations of amine in the urine, 50 cc of urine and the entire ether extract will give an adequate intensity of color. With higher concentrations of the amine, aliquot fractions of the ether extract may be used for the determination, or the final toluene extract may be diluted further with known amounts of toluene until the color intensity or shade falls within the range of the standards, and the final reading is multiplied in accordance with the dilution.

TABLE 1—Composition of Standards for the Determination of 2,6-Dinitro-4-Aminotoluene

% Dinitro-4-Aminotoluene (Amount in Mg in 10 Cc)	Methyl Orange Solution in Cc	Buffer Solution in Cc
0.00	0.0	10.0
0.01	0.2	9.8 buffer No 1
0.05	0.6	9.4 buffer No 1
0.05	1.0	9.0 buffer No 2
0.07	1.4	8.6 buffer No 2
0.09	1.8	8.2 buffer No 2
0.11	2.2	7.8 buffer No 2
0.13	2.6	7.4 buffer No 2
0.15	3.0	7.0 buffer No 2

TABLE 2—Determination of 2,6-Dinitro-4-Aminotoluene in Human Urine Containing Known Amounts of the Amine

Amine Added in Mg per 50 Cc.	Amine Recovered in Mg per 50 Cc
0.1	0.10 to 0.14
0.2	0.14 to 0.18
0.3	0.23
0.4	0.36 to 0.44
0.5	0.45
0.6	0.66
0.7	0.77
0.8	0.72 to 0.83
0.9	0.99
1.0	1.1

Table 2 gives the results of determinations made by this method with human urines containing known amounts of 2,6-dinitro-4-aminotoluene. It shows that the method allows a sufficiently accurate estimation of the amount of amine excreted.

It should be pointed out that this method is not specific for 2,6-dinitro-4-aminotoluene because any primary aromatic amine which is soluble in ether will be diazotized and coupled with the formation of a pigment. However the extraction of the coupled product with toluene prior to the colorimetric determination affords a certain specificity in that no compound tested so far is as soluble in toluene as 2,6-dinitro-4-aminotoluene. After diazotization and coupling sulfanilamide for example will remain mainly in the aqueous phase since its solubility in toluene is rather low. Of other drugs tested the ingestion of acetanilid will cause very little and the ingestion of aminopyrine will cause no interference with the determination of the amine. While no normal urine tested has yielded a color after diazotization and coupling occasionally some urine will contain a pigment which passes unchanged through the various procedures into the final toluene extract. If no amine is present in the urine this color will not be changed after diazotization and coupling but in the presence of amine there will be a change of the color of the solution after diazotization and coupling. In such urines the evaluation of the amount of amine present will require some discretion and the determination should be repeated after a few days.

SUMMARY

A method has been devised for the determination of 2,6-dinitro-4-aminotoluene in the urine of workers exposed to trinitrotoluene, and its limitations have been determined. This method has the advantage over the Webster test in that the final color is stable and allows a quantitative determination.

TOXIC REACTIONS TO SUCCINISULFATHIAZOLE

RICHARD C. CLAY, M.D. AND KENNETH L. PICKRELL, M.D.
BALTIMORE

With the establishment of the bacteriostatic value of the different sulfonamides in various infections, it was a logical step to seek for a drug of this group which would control the normal and pathologic flora of the intestine. The fundamental requirements of such a drug were that it should be an effective bacteriostatic agent against coliform organisms in their natural habitat that it should be so slightly absorbed that an adequate concentration in the bowel might be maintained, and that it should be nontoxic to the human organism. Marshall and his associates¹ first introduced a drug appreciably water soluble but poorly absorbed, sulfanilylguanidine, and showed its clinical usefulness in bacillary dysentery. Subsequently Poth,² Firor,³ and others introduced succinylsulfathiazole as an intestinal antiseptic and established the fact that in adequate dosage it lowered the coliform count of the stools significantly in over 90 per cent of cases in dogs and men. They also showed that even in large doses the drug is poorly absorbed reaching levels of less than 2 mg per hundred cubic centimeters in the blood when given alone in their series. No evidence of toxicity was encountered.

On the basis of a series of 50 patients who subsequently underwent surgical procedures involving the large bowel and who were treated preoperatively with succinylsulfathiazole, Poth⁴ concluded that administration of the drug largely eliminated complications due to infection and rendered the convalescence smoother and shorter than in untreated patients, though control cases are not presented in this study. As a further instance of the usefulness of this sulfonamide Poth, Chenoweth and Knotts⁵ have reported a series of 20 cases of bacillary dysentery in which the age ranged from 8 weeks to 83 years, all successfully treated with succinylsulfathiazole. More recently Smyth and his associates⁶ have reported successful therapy of 12 out of 14 cases of Flexner type dysentery using succinylsulfathiazole.

TOXICITY OF SUCCINISULFATHIAZOLE

Throughout the reports on the use of this drug emphasis is placed on its freedom from toxicity, and it is advertised as a clinically nontoxic intestinal bacteriostat. Admittedly unfavorable reactions are uncommon—much more so than with sulfanilylguanidine, but toxic phenomena do occur. Welch, Matis and Latven⁷ in an extensive toxicologic study on monkeys showed that administration by stomach tube of up

to 5 Gm per kilogram daily of succinylsulfathiazole in six equal doses produced blood levels of 30 mg of the drug per hundred cubic centimeters and 0.8 mg of free thiazole per hundred cubic centimeters and led to no toxic effects. Intravenous administration of the sodium salt in doses up to 1 Gm per kilogram produced total drug levels as high as 170 mg per hundred cubic centimeters and resulted in excretion of urine containing as much as 12 Gm of succinylsulfathiazole per hundred cubic centimeters with frequent crystalluria whose intensity varied with *ph* as well as with urinary drug concentration, the more acid specimens showing heavier crystalline deposits. Some urines showed massive crystalluria with 4 per cent drug concentrations while others failed to show any with 10 per cent concentrations. These authors reported hematuria in occasional crystal loaded urines, but it is not clear whether this was gross hematuria and whether all specimens were examined microscopically for blood.

No previous reports of hematuria in man attributable to succinylsulfathiazole have been encountered, but Poth¹ mentions infrequent complaints of headache, dizziness and anorexia. He cites a single case in which 0.25 Gm (presumably per kilogram) of the drug had been administered daily for eight days for chronic ulcerative colitis with complaints of headache, nausea, vomiting, chills and arthralgia associated with a temperature of 103 F, lesions similar to erythema nodosum on the anterior surfaces of the legs, moist rales in the chest and a 5 per cent eosinophilia. A week later, when the reaction had subsided, administration of a single gram of sulfathiazole produced a temperature of 103.6 F and the symptoms and signs described in the first reaction. Smyth and his associates⁶ observed sulfonamide crystals in the urine of 10 to 14 patients treated with succinylsulfathiazole for Flexner dysentery but none in the urine of 10 patients hospitalized for other causes and given succinylsulfathiazole as controls.

The records of the Johns Hopkins Hospital show that 100 hospitalized adult patients have received succinylsulfathiazole for periods up to five weeks for such diverse conditions as colonic carcinoma, diverticulitis, bacillary dysentery, accidental perforations of the bowel, ureterosigmoidostomy, chronic fecal fistula and rectovaginal fistula. While the dosage in the vast majority of cases was, as recommended by Poth and Knotts,⁸ 0.25 Gm per kilogram as an initial dose and as a daily dose divided into six equal portions, some few patients have received less than this while several have received much more. One patient with a chronic postoperative cecal fistula was given 81 Gm daily by mouth and a similar quantity by colostomy for two days, after which the dosage was gradually diminished to 27 Gm daily by mouth. The drug was discontinued only after seventeen days without reaction. In this series of 100 cases, aside from a case of conjunctivitis questionably due to drug, there were only two unfavorable reactions: the first, a case of fever, rash and arthralgia similar to Poth's case, and the second a case of crystalluria with hematuria. The following are brief case reports.

REPORT OF CASES

CASE 1—A Negro woman aged 44 was referred to the hospital on March 15, 1943 by her physician, who felt a mass in the left lower quadrant of the abdomen. She had had symptoms of chronic low bowel obstruction for eighteen months and had been hospitalized elsewhere for six weeks for acute obstruction six months previously, being treated by bland diet and enemas. On discharge she herself noticed a small mass in the left lower quadrant of the abdomen, and this grew progressively larger while the patient lost 30 pounds (13.6 Kg). On admission to the Johns Hopkins Hospital she was afebrile, the bowels were unobstructed, the stools were benzidine positive, and a mass the size of a grapefruit was palpable in the left side of the abdomen. A barium sulfate enema revealed a filling defect in the left side of the colon. The patient was given 15 Gm of succinylsulfathiazole immediately and started on a regimen of 4 Gm of the drug every four hours. The temperature had begun to rise four hours after the initial dose and reached 105.4 F orally in twenty-four hours. The chest showed no abnormal physical signs, the urine contained

no white cells and the abdominal findings were unchanged. The blood drug level of free thiazole was 1.0 mg per hundred cubic centimeters. The drug was discontinued twenty hours after it was started and after the patient had taken 39 Gm. The temperature continued elevated, reaching 105.8 F twenty-four hours after discontinuance of the drug. Meanwhile, aside from being warm, the patient felt well and ate with good appetite while the temperature was 105 F. Following discontinuance of the drug the temperature, as stated, remained elevated twenty-four hours and then began to fall. Two days after the maximum elevation the temperature was normal. In order further to confirm the diagnosis of drug reaction the patient, when afebrile, was given a single dose of 5 Gm of succinylsulfathiazole. The temperature gradually rose with fluctuations, reaching 102.6 F two days later, after which it gradually fell to normal. In addition, an hour after the drug was given a pruritic morbilliform rash appeared on the flexor surfaces of the arms and the adductor surfaces of the legs, and generalized myalgias and arthralgias were bitterly complained of. The rash persisted three days and the other symptoms four days.

At operation an adenocarcinoma of the descending colon was resected, and the transverse colon was anastomosed end to end with the sigmoid. There were metastases in the preaortic nodes. The postoperative course was entirely uneventful, the patient got up on the tenth postoperative day and went home a week later, completely asymptomatic.

CASE 2—A man aged 54, a Czechoslovakian, was first admitted to the Johns Hopkins Hospital in May 1939 with symptoms and signs of complete low bowel obstruction for four days. At operation adhesions about the terminal ileum were released, but distention persisted postoperatively. Two weeks after discharge obstruction recurred and laparotomy revealed a carcinoma of the sigmoid, which was resected by the Muculicz procedure. The patient was discharged with an excellently functioning colostomy, which was closed successfully seven months later. Two and one-half years later he was again admitted with a story of partial obstruction for ten days, and a barium sulfate enema showed a constriction in the sigmoid. On Sept. 28, 1942 the patient was given 16 Gm of succinylsulfathiazole and started on a regimen of 2.5 Gm every four hours. On the sixth day, October 3, he complained of dull right lumbar pain and his urine, which had been normal on admission as on each previous occasion, was grossly bloody and contained sulfonamide crystals. The drug was discontinued but a blood level was not obtained until two days later, when it was 3.83 mg of free thiazole per hundred cubic centimeters. Microscopic hematuria of diminishing intensity was noted for eight days after the drug was discontinued, and sulfonamide crystals were detected in the urine as late as the fifth day after onset of hematuria. On the fifth day the blood level was 1.3 mg of free thiazole per hundred cubic centimeters.

A 20 cm segment of large bowel with recurrent tumor, which was found to have invaded the abdominal wall, was resected after the hematuria subsided. End to end anastomosis was carried out. The wound became infected and had not completely healed when the patient was discharged with normal bowel function thirty-six days postoperatively.

COMMENT

Case 1 represents an instance of drug fever which, while not the first reported attributable to succinylsulfathiazole, is unusual in that it occurred so soon after initiation of therapy. It also indicates that, as with other sulfonamides, arthralgia and rash may appear during the course of succinylsulfathiazole therapy. The second case is, so far as can be ascertained, the first one of hematuria attributable to this drug, although crystalluria, which accompanied the hematuria, has previously been observed. The small total number of patients followed warrants no conclusion as to the frequency of such unfavorable reactions to be anticipated, but the fact that they do occur makes it imperative that patients receiving the sulfonamide be carefully watched and frequent urinalyses carried out. While anemia attributable to succinylsulfathiazole did not occur in this series, the supposition seems warranted by analogy to related drugs that it will occur, and frequent blood examinations are certainly indicated.

Special Article

THE DRUG TREATMENT OF MALARIA, SUPPRESSIVE AND CLINICAL

The following article from the Office of the Surgeon General of the Army has been distributed as Circular Letter No. 153

1 *Efficacy of Atabrine, Quinine and Plasmochin*—a. Available evidence indicates that atabrine is as effective as quinine (or more so) both in suppressive use and in the treatment of clinical attacks. No available drug or plan of administration can be expected to prevent relapses in all cases (see paragraph 6). Recent studies have shown that the plasma level of the drug is fundamental in determining its efficacy. Under ordinary conditions the rates of absorption of the two drugs are not significantly different. Quinine is localized in the tissues to a smaller extent than atabrine and effective plasma concentrations therefore are usually attained shortly after the beginning of its administration. Atabrine on the other hand at first is taken up to a much larger extent by the tissues so that effective concentrations in the plasma are reached only as certain tissues become more or less saturated. On the usual dosage plans, therefore quinine reaches an effective plasma level more rapidly than atabrine. In order to attain effective concentrations of atabrine in the plasma, it is necessary to give relatively large initial doses (as is done with the sulfonamides) or to wait for a varying period while the drug accumulates. Further discussion of the desirable methods of giving atabrine will be found under Suppressive Treatment (paragraph 4) and Clinical Treatment (paragraph 5). Since a great many different plans of giving atabrine and quinine have been tested, little can be gained by numerous modifications which serve only to confuse the problem.

b. Plasmochin cannot be used for suppressive treatment, since in safe doses it has very little effect on schizonts. For the same reason it fails to control clinical attacks of malaria; hence plasmochin alone cannot be used in clinical treatment. This drug has some degree of special action in the destruction of gametocytes an effect which does not influence the course of the disease in the patient but might be of value in controlling the spread of the disease. It has not been established, however that the use of plasmochin constitutes a practical method of malaria control. It is also stated that the incidence of relapses is less when plasmochin is given after atabrine or in conjunction with quinine, but this is a matter of controversy and the claim has not been borne out by recent experience. After consideration of the possible advantages and the toxic effects (see paragraph 2c), in addition to the prolongation of hospitalization, the routine use of plasmochin is not advised.

2 *Untoward Effects of Atabrine, Quinine and Plasmochin*—Each of these drugs is capable of producing toxic reactions. Occasional individuals are peculiarly intolerant of each.

a. Mild disagreeable reactions from atabrine may occur in a certain percentage of individuals given the drug for suppressive treatment. When such symptoms occur they usually follow one of the first few doses. They are much more apt to occur when atabrine is

given between meals. They may consist of nausea, abdominal cramps or occasionally headache, vomiting and diarrhea. These symptoms may be prevented in most cases by giving sodium bicarbonate or sweetened drinks such as tea with the atabrine. They are never serious and almost invariably disappear if the drug is continued. In a small percentage of some groups of patients receiving clinical treatment mild excitement has been observed. Toxic symptoms of any type are unusual in association with the treatment of clinical attacks with atabrine. There are on record only a very few instances in which hepatic disease may have been associated with therapeutic doses of atabrine and none with suppressive treatment. Approximately one third of the individuals taking atabrine develop a yellow discoloration of the skin. This is caused by the deposit in the skin of atabrine (which is a dye). It does not represent hepatic damage, is not dangerous and is not an indication for discontinuing the drug. The discoloration disappears within a few weeks after the drug is stopped. Extensive investigation has failed to show that atabrine in the usual doses has any effect whatever on flight capacities of flying personnel. Atabrine in suppressive doses has been taken by large groups for a year or more without known lasting untoward effect.

b. Outstanding untoward results of quinine which appear in most patients following therapeutic doses of the drug are tinnitus, impairment of hearing, dizziness, tremor and palpitation. They have been used as an index that the drug is being absorbed and is exerting an effect. In milder degree some of these symptoms may be seen during suppressive treatment. Some aviators have found them troublesome. The more unusual severe untoward effects of quinine are generally the result of individual hypersensitivity or of unnecessarily large doses.

c. The margin of safety between therapeutic and toxic doses of plasmochin is small. The toxic symptoms include abdominal pain, nausea, vomiting, cyanosis, headache, dizziness and drowsiness, hemoglobinuria, jaundice and acute yellow atrophy of the liver are rarer but very dangerous effects.

3 *Conservation of Quinine*—The limitation of the supply of quinine is so great that the use of the drug must be restricted as directed in S. G. O. Circular Letter No. 179 Dec 21, 1942. Quinine should never be used for suppressive treatment except in emergencies when atabrine is not available and, exceptionally, for the very few individuals who cannot tolerate atabrine. Its use for clinical attacks should be restricted to the following types of cases:

a. Severe infections with *Plasmodium falciparum* in which intravenous therapy is deemed essential.

b. Serious intolerance to atabrine.

c. When atabrine is not available.

d. Following repeated relapses in spite of atabrine therapy, when a change of drug is considered highly desirable. In such cases a complete course of quinine may be used as described in paragraphs 5 b (2) and 6 c.

4 *Suppressive Treatment*—a. Drug suppressive treatment is an emergency procedure which should be employed only when troops must accomplish a mission in an area where there is a substantial risk from malaria and where protection by mosquito control measures is not possible. At present there is no drug known which in safe doses will prevent mosquito borne infection.

with malaria. However, atabrine, taken regularly in proper doses, suppresses clinical symptoms for varying periods of time and enables men to remain active in spite of infection which otherwise would incapacitate them. For this reason suppressive treatment has its chief use among troops that must maneuver or fight in malarious regions and cannot be given full protection from mosquitoes. When these troops return to sanitized areas, suppressive treatment should be discontinued as soon as feasible.

b For suppressive treatment to be effective it is essential that the drug be taken regularly. Experience has shown that a roster check with each dose is the only practical means of accomplishing this result. This is the responsibility of the unit commander.

c In general, suppressive treatment should be instituted as soon as possible after arrival in an unsanitized malarious area. There are, however, certain advantages in starting the administration of atabrine in advance of exposure when it is practicable to do so. First, opportunity is afforded to discipline officers and men in establishing the routine of taking atabrine. Second, such disagreeable reactions as may occasionally accompany the first few doses are experienced before the men engage in combat activities. Third, recent experimental studies show that with the suppressive dosage of atabrine recommended in paragraph 4f the maximum plasma concentration of the drug is not attained until after the third week. Hence the institution of atabrine suppressive treatment two weeks in advance of exposure may be advantageous in that a high plasma level of the drug is achieved by the time clinical symptoms might be expected to appear. However, when men must travel to their destination by boat, seasickness may be a contraindication to the institution of atabrine suppressive treatment in the period preceding arrival in the malarious area.

d When suppressive treatment is discontinued, most of the men who have been infected will develop clinical malaria (the majority within two or three weeks) and will then require clinical treatment (see paragraph 5). Consequently, suppressive treatment should not be stopped until the men have returned to a base where adequate medical care is available. When a large force returns from a hyperendemic area it may be wise to stagger the cessation of suppressive treatment in order that hospital facilities may not be overtaxed.

e *Occurrence of Clinical Symptoms During Suppressive Treatment*—In highly malarious regions, especially under the stress of combat, suppressive treatment may fail to prevent clinical symptoms in a certain percentage of cases. These cases should be given a course of clinical treatment (see paragraph 5), following which the suppressive treatment should be resumed, if still indicated. Many instances of so-called break-through of clinical symptoms can be traced to failure of the individual to take the drug regularly.

f *Administration of Atabrine for Suppressive Treatment*—The recommended method is to give 0.1 Gm of atabrine (1½ grains, i.e. one tablet) once daily at the evening meal six days each week (total 0.6 Gm per week).

g An alternative method of suppressive atabrine administration, which has been satisfactory in some areas, is to give 0.05 Gm of atabrine (¾ grain, i.e. one-half tablet) once daily at the evening meal six days

each week, and a dose of 0.1 Gm (1½ grains, i.e. one tablet) at the evening meal on the seventh day (total of 0.4 Gm per week).

h Quinine, because of the limited supply available, should not be used for suppressive treatment except in the few cases mentioned (paragraph 3). Recommended dosage is 0.6 Gm (10 grains) of quinine sulfate daily at the evening meal.

i Plasmochin should not be used for suppressive treatment at any time.

5 *Treatment of Clinical Attacks*—a *Diagnosis*
(1) Malaria should be suspected not only in patients with periodic chills and fever but also in any obscure illness, febrile or nonfebrile, in endemic regions. The symptoms of malaria may vary in different cases from mild headache or diarrhea to severe chills and fever, and to delirium or coma.

(2) In general, the diagnosis must be based on the actual finding of parasites in the blood. In each suspected case, examine the blood as soon as possible. Thick smears are preferable because the parasites are concentrated. Each smear should be examined carefully for at least five minutes before being pronounced negative. Thin smears should also be made for use when species diagnosis cannot be made from thick smears; each smear should be examined carefully for at least fifteen minutes. In *P. falciparum* infections estimate the proportion of infected erythrocytes; when 5 per cent or more erythrocytes are infected, treat as you would a comatose patient [see paragraph 5c (2)]. If parasites are not found, make smears on successive days, because the symptoms in a first attack may appear when the density of parasites is low and because in *P. falciparum* infections there may be very few parasites in the circulating blood during the second twenty-four hours of each asexual cycle.

(3) Even in severe *P. falciparum* infections with cerebral symptoms, including coma, it may be difficult to demonstrate parasites. Suspect as *P. falciparum* malaria every case of febrile illness in which coma or medical shock occurs in a patient in or from an endemic area. Excessive fatigue, headache and fever are frequently the only prodromal symptoms of cerebral malaria. This form may simulate acute alcoholism or the patient may be maniacal, requiring morphine. During the stage of onset the temperature is often little elevated and in the presence of coma it may be normal or subnormal. If the facilities for immediate examination of blood smears are not available, malarial therapy should be immediately instituted in such emergency cases.

(4) When treatment is started before parasites are demonstrated, it should not be continued beyond a period of one week, unless the diagnosis is confirmed by finding parasites. It is rare that the fever of malaria fails to respond to adequate doses of atabrine or quinine.

b *Uncomplicated Malaria* (patient able to return oral medication). Be sure that each patient takes the drug as ordered. Each dose should be taken in the presence of a nurse or medical officer. Even though vomiting has not occurred, occasional patients receiving oral therapy fail to absorb the drug adequately. If the diagnosis has been confirmed, patients who are seriously ill and do not respond should receive intramuscular or intravenous therapy, as described in paragraph 5c, until a therapeutic response is obtained. In

occasional cases especially of *P. falciparum* infection, in which fever is persistent method (1) or (2) should be continued beyond the period of seven days at the discretion of the medical officer.

(1) The method of choice is to use atabrine alone. In accordance with the principles outlined in paragraph 1 a atabrine should be given in relatively large initial doses followed by smaller maintenance doses. Recommended dosage atabrine hydrochloride 0.2 Gm (3 grains) and sodium bicarbonate 1 Gm (15 grains) by mouth with 200 to 300 cc of water (or an equal amount of sweetened tea or fruit juice) every six hours for five doses followed by 0.1 Gm (1½ grains) three times a day after meals for six days (total 2.8 Gm in seven days).

(2) If atabrine is not available use quinine alone as follows quinine sulfate 1 Gm (15 grains) by mouth three times a day after meals for two days followed by 0.6 Gm (10 grains) three times a day after meals for five days (total 1.6 Gm in seven days).

(3) Plasmochin may be given in connection with either of the foregoing treatments, however, its routine use is not advised. If plasmochin is given, the patient must be hospitalized and closely observed. The dosage given below should not be exceeded. Plasmochin may be given immediately following atabrine (not with it) or along with quinine on the last days of treatment with that drug. The course consists of plasmochin 0.01 Gm (¼ grain) by mouth three times a day after meals for four days except for the debilitated patient, who should receive only two doses a day. Each dose of plasmochin should be accompanied by at least 1 Gm (15 grains) of sodium bicarbonate. The fluid and sugar intake should be liberal during and for some days after the course. Discontinue plasmochin at once if any toxic symptoms appear.

c Severe Malaria or Malaria Complicated by Vomiting, Coma or Other Serious Disorders. In these cases, and whenever a patient cannot retain or fails to respond to oral medication atabrine or quinine should be given parenterally by one of the methods described below [paragraph 5 c (2) (a) or (b)].

(1) If vomiting is present, take general measures to control it. Do not allow solid food just before a febrile paroxysm is expected. If there is nausea or vomiting, sips of alkaline water may be helpful. If vomiting is frequent and troublesome, the intravenous administration of 5 per cent dextrose in isotonic solution of sodium chloride is indicated, as many patients who vomit become dehydrated and develop acidosis. From 200 to 400 cc may be injected by the usual technic, this injection may be repeated if necessary, or larger amounts may be given by the continuous drip method (at the rate of 50 drops per minute). When dextrose is administered in this way, it should be supplemented with 1 mg of thiamine hydrochloride for each 25 Gm of dextrose.

(2) Coma may be present or imminent in cases of *P. falciparum* infection, even though parasites are not found in the blood smear. This condition constitutes a grave emergency. On reasonable suspicion of the diagnosis, parenteral treatment must be immediately instituted. The intravenous administration of quinine as described in paragraph 5 c (2) (b) is preferable in the light of present knowledge, but it is possible that the intramuscular injection of atabrine is equally effective.

Recommended parenteral methods are as follows¹

(a) Atabrine dihydrochloride 0.2 Gm (3 grains) in 5 cc of sterile distilled water injected intramuscularly with the usual precautions into each buttock (total 0.4 Gm or 6 grains). If necessary one or two additional doses of 0.2 Gm (3 grains) may be given intramuscularly at intervals of six to eight hours. As soon as the patient can take and retain oral medication atabrine should be given by mouth in such doses as to give a total by both routes together of 1.0 Gm in forty-eight hours followed by 0.1 Gm three times a day after meals for five days (total 2.8 Gm in seven days).

(b) Quinine dihydrochloride 0.6 Gm (10 grains) in sterile isotonic solution of sodium chloride 300 to 400 cc (minimum 200 cc) injected intravenously with the usual precautions especially avoiding speed. If necessary, there should be no hesitation to cut down to the vein. This treatment may be repeated in six to eight hours if the situation demands it. When the patient can take and retain oral medication give a complete course of atabrine (preferable) or quinine by mouth as described for uncomplicated cases in paragraph 5 b.

d General Care (1) Keep the patient in bed. Maintain fluid intake at 3 to 4 liters per twenty-four hours, using the intravenous route if necessary. Since many patients with malaria may lose a great deal of salt be sure that the intake of salt is adequate giving supplementary amounts as may be indicated. Relieve chills by hot water bags and blankets. Relieve high fever by cold sponges and packs (avoid antipyretics). If a sedative is necessary, use one of the barbiturates. In all cases of *P. falciparum* infection observe the patient closely for signs of cerebral or circulatory collapse.

(2) Patients with clinical malaria or parasitemia should be in screened wards or under mosquito bed nets (with care that they do not sleep against the nets).

(3) In convalescence give a generous high vitamin diet, together with ferrous sulfate 0.6 Gm (10 grains) three times a day after meals for at least two weeks (preferably longer).

6 Relapses—A Occurrence. A certain percentage of patients with malaria suffer recrudescences or relapses in spite of any available treatment. The incidence and persistence of recurrences are greatest in *P. vivax* infections. For this reason the original incidence of the species of infection cannot be estimated from their distribution in a group of patients with recurrent clinical activity. The first free interval may be as short as two or three weeks, later on the intervals grow longer and may be many months. With each successive relapse the chance that it will be the last increases. This is one reason why the evaluation of treatment plans in relapses is difficult.

b Diagnosis. The diagnosis of late relapses is often difficult. As long as a patient remains in an endemic area the distinction between reinfection and relapse is practically impossible. Relapses should be suspected in all patients who have a history of malaria. Exposure, strenuous activity, alcoholic indulgence, trauma and surgical procedures frequently precipitate serious recurrences. It never occurs under these circumstances.

¹ In emergency when atabrine and quinine for parenteral use are not available quinine sulfate may be given by rectum in a dose of 1 or 2 Gm mixed with a pinch of starch enough to run through a rectal catheter. This route should not be used more than once or twice.

or without other explanation in men in or from endemic areas malaria should be suspected. If facilities for blood examination are not available, treatment should be instituted without delay. It is desirable, however, to prove the diagnosis, especially when relapses are suspected after a long interval. In a certain proportion of latent cases (but not all) the subcutaneous injection of 0.5 cc of 1:1,000 solution of epinephrine results in finding parasites in the peripheral blood when they are not otherwise seen. In suitable cases this method may be tried. Routine efforts by this or other means to bring out parasitemia or to precipitate relapses in large groups of men who are free of symptoms are inadvisable.

c Drug Administration There is no reason to believe that treatment with atabrine or quinine in the absence of parasitemia and clinical relapse has any influence on the future occurrence of relapses; treatment is not recommended, therefore for patients who are free of symptoms or those in whose blood parasites are not found. In general, the treatment of relapses should be the same as that of first attacks. Prolongation of maintenance doses of atabrine to a total period of two or three weeks may be tried. In cases of repeated relapses in spite of atabrine therapy, when it is especially desired to try to prevent further relapses, the quinine treatment described in paragraph 5 b may be used and continued with a daily dose of 0.6 Gm (10 grains) to a total period of three or four weeks, but such instances must be kept to a minimum in order to conserve quinine.

7 Records, Follow-Up—In order to accumulate information which will be of value in determining the efficacy of treatment plans, medical officers responsible for the care of patients with malaria should use a few well defined plans, such as those given in this circular letter. Patients should fall into a few clearcut treatment groups, so that the results can be gathered together from time to time for study. Data should be recorded showing the whole course of the patient's malarial history. Only by means of information which is continuous can the need of prolonged follow-up be met. The following points are illustrative of basic data which are required.

a Previous History

(1) Dates of first entry into endemic region and of any subsequent return to an endemic area

(2) Suppressive treatment at various times, dates, drug, doses, regularity, intermissions

(3) Clinical attacks, dates, interval following cessation of suppressive treatment, break-through during suppressive treatment, courses of clinical treatment in detail, duration of symptoms, intervals between relapses

(4) Date of removal from endemic area

(5) Date of arrival in continental United States

b Present attack or relapse

(1) Diagnosis by smear, including malarial species

(2) Dates of beginning of symptoms, institution of treatment and cessation of fever

(3) Rate of disappearance of parasites and date of their final disappearance

(4) Full clinical notes, including symptomatology and exact plan of drug administration

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
AUSTIN E SMITH, M D, Secretary

THE STATUS OF DICHLOROPHENARSINE HYDROCHLORIDE TRADE NAMES CLORARSEN, PHENARSINE HYDROCHLORIDE

Since January 1936 the antisyphilitic agent mapharsen has been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies. Mapharsen (Parke, Davis & Co.) is a brand of 3-amino-4-hydroxyphenyl arsine oxide hydrochloride. Reactions following the use of this agent are claimed to be less severe than those observed after the use of arsphenamine and neoarsphenamine.

In recent literature may be found reports of an arsenical antisyphilitic agent which apparently was discovered in the early part of this century but was cast aside as being too toxic for clinical use. Some years later there were published reports on its use in animals and in the treatment of jaws and human syphilis. It was not until 1941 that 3-amino-4-hydroxyphenyl dichloro-arsine hydrochloride was found satisfactory for the treatment of syphilis, apparently the earlier studies were based on the use of an unbuffered compound which would provide a very low pH.

The preparations now available on the market contain sufficient alkaline buffering agent to make neutral a prepared solution for injection. They contain approximately 26 per cent of trivalent arsenic. At least four firms (Abbott Laboratories, Parke, Davis & Company, E. R. Squibb & Sons, Winthrop Chemical Company, Inc.) have been licensed to manufacture and make available for interstate commerce this substance, which is marketed at the moment as Phenarsine Hydrochloride (Winthrop) and Clorarsen (Squibb). The name proposed by the U. S. Pharmacopeia is Dichlorophenarsine Hydrochloride. One firm uses sodium citrate as a buffer, another sodium carbonate. On the addition of sterile distilled water to an ampul containing the mixture of dry dichlorophenarsine hydrochloride and alkaline buffer a reaction takes place with the result that arsenoxide is supposed to be formed. It has been claimed that the latter agent is the therapeutically active part of the compound.

In 1941 the therapeutic possibilities of buffered solution of dichlorophenarsine hydrochloride were presented in a report¹ based on a series of animal experiments and on a clinical study of 171 patients treated over a period of two years. The authors concluded that 3-amino-4-hydroxyphenyl dichloroarsine hydrochloride buffered with sodium citrate is "a safe and effective drug in the treatment of syphilis as judged by (1) rapid production of darkfield negativity of early lesions, (2) prompt healing of early lesions, (3) effectiveness in producing seronegativity in early syphilis, (4) low percentage of relapses, (5) low incidence of abnormal spinal fluids in early syphilis, (6) absence of severe immediate reactions to its administration and relatively low number of reactions in general."

The probable toxicity of the drug was determined by Tompsett and others in mice and rabbits, and no lesions were found in killed animals that could be attributed as due to the toxic effect of the drug. The clinical material for the study consisted of 171 patients: 117 had early, 38 had late latent syphilis, 4 had asymptomatic neurosyphilitic lesions and 12 had various syphilitic lesions. The general scheme of treatment was that of the usual combined bismuth and arsenical treatment except that treatment with the drug under investigation was generally prolonged. Only 1 patient had an infectious relapse. Serologic relapse was not encountered. Gastrointestinal, cutaneous and

¹ Tompsett, R. R., Downs, W. G., McDermott, Walsh, and Webster, Bruce. The Use of Clorarsen in the Treatment of Syphilis. *J. Pharmacol. & Exper. Therap.* 73: 412 (Dec.) 1941.

syncope reactions occurred in 51 cases. However there were no severe immediate reactions. There were no deaths. The gastrointestinal reactions included nausea, vomiting and diarrhea but rarely was it necessary to discontinue the drug. Fainting shortly after injection of the drug was observed in 4 cases but in all the patient was well tolerated later. There were no nitritoid reactions. The other reactions included in part exfoliative dermatitis (1), fixed arsenical eruption (1), papular dermatitis (2), pruritus (1), angioneurotic edema (1), chills, fever, headache (2), jaundice (1), generalized pruritus (1), questionable purpura (1).

Long² in reporting on the use of phenarsine hydrochloride¹ in the treatment of 90 patients with syphilis over a period of twenty months which involved 2033 injections declared that the drug results in effects equal to those obtained from any of the arsenicals in general use and the reactions are less frequent and less severe. There were 336 reactions from 2033 injections: the types of reaction included gastrointestinal (288), headache (4), depression (2), malaria (20), salivation (21) and pruritus (1). Early and late syphilis was treated.

Guy and his co-workers³ conducted toxicity tests and curative tests on rats and concluded that the results obtained from the use of phenarsine hydrochloride did not differ materially from those obtained with mapharsen. The therapeutic index of both compounds was declared as about 28. Clinically they investigated the drug by administering 2581 injections to 233 patients. The administration of 1 injection to 4 patients with primary lesions caused the disappearance of spirochetes from the lesions according to darkfield examinations, within twenty-four hours. Cutaneous manifestations disappeared within an average of fourteen days. As have other investigators, Guy and his co-workers observed mild gastrointestinal upsets. They also experienced one nitritoid reaction and one Herxheimer reaction. Complete blood studies showed no evidence of granulocytopenia or anemia. Routine urinalysis revealed no abnormal urinary findings.

Kampmeier and Henning⁴ reporting their findings on 251 patients, which involved 4348 doses, evaluated the efficacy of the drug on the rapidity of producing darkfield negativity, the healing of lesions, the reversal of serologic tests and a low frequency of spinal fluid abnormalities. They found that a single therapeutic dose would usually produce darkfield negativity within twenty-four hours, acute lesions healed promptly, and 37 cases of early syphilis presented negative spinal fluids after two or more courses. No serious untoward reactions were encountered; nausea, vomiting and diarrhea were the most common reactions. Some patients who had had untoward reactions with other arsenical preparations were able to tolerate the drug under investigation without reaction.

A confidential report submitted to the Winthrop Chemical Company by a syphilologist in the East presented a study of 282 patients. The total number of injections of 'phenarsine hydrochloride' usually administered weekly was 1340, an average of 48 injections per patient. Fifteen patients received bismuth concurrently. The usual dosage for men was 0.06 Gm and for women 0.04 Gm. Twenty-two previously untreated patients with primary or secondary syphilis received injections of 'phenarsine hydrochloride' and a bismuth salt. Darkfield examinations of the lesions showed satisfactory responses for the disappearance of the infecting organism. Reactions per thousand injections among the 282 patients provided the following incidence: nausea 42, vomiting 69, diarrhea 19, headache 50, dizziness 10, chill 1, palpitation or mild precordial distress 2, pain in gums 10, sore arm 13, pruritus 18, urticaria 4, dermatitis 2, jaundice 2, agranulocytosis 1. The author stated that the reactions were for the most part of minor significance.

The Council on Pharmacy and Chemistry has had under consideration for some time a brand of dichlorophenarsine hydro-

chloride. Consideration has not been completed pending the receipt of certain additional information, particularly that relating to stability. The Council has had reason on past occasions to give considerable attention to the stability of certain popular antisyphilitic agents and demands that sufficient evidence be supplied for the brands of dichlorophenarsine hydrochloride before any will be accepted for inclusion in New and Nonofficial Remedies. At present, several interested persons claim that this agent is as stable as or more stable than oxophenarsine hydrochloride but the Council is withholding its final decision pending the receipt of more evidence. The four firms who are licensed to manufacture dichlorophenarsine hydrochloride were invited to supply evidence regarding stability but to date have not submitted adequate protocols. The National Institute of Health has permitted a dating period of three years for 3-amino-4-hydroxyphenyl dichloroarsine hydrochloride (dichlorophenarsine hydrochloride), an indication that this body has procured evidence of stability which is satisfactory for a definite dating period. However, because the Subcommittee on Venereal Disease of the Committee on Medicine of the National Research Council and the Committee on Drugs and Medical Supplies concurred in a recommendation that the Council be requested to prepare a statement on the status of dichlorophenarsine hydrochloride and oxophenarsine hydrochloride (N N R brand mapharsen), the Council on the basis of information in the literature and that supplied by the National Research Council and one interested manufacturer adopted for immediate publication this general report and the appended statement of dosage. This statement may have to be revised as experience demands. At present, no brand of dichlorophenarsine hydrochloride stands accepted for inclusion in N N R although the Winthrop Chemical Company has submitted its brand. Another brand which is available in interstate commerce, but which has not been submitted to the Council is Clorarsen made by E R Squibb & Sons.

During its consideration of these agents the Council questioned whether the medical profession will accept generally, the names Dichlorophenarsine Hydrochloride and Oxophenarsine Hydrochloride, which have been proposed for inclusion in U S P XII first supplement, as official names for 3-amino-4-hydroxyphenyl dichloroarsine hydrochloride and 3-amino-4-hydroxyphenylarsine oxide hydrochloride respectively, phenarsine hydrochloride having been preempted as the name for a theoretical compound on which will be based new compounds. The Council is of the opinion that other nonproprietary designations might be chosen to advantage names which would be less conducive to the coining of 'tricky' names for sales promotion and which would be easier for the practicing physician to remember. Consideration might be given to applying the name 'phenarsine' to the structural unit which has been designated phenarsine hydrochloride since the possibility is remote that salts other than the hydrochloride will ever be utilized in the preparation of such compounds. It thus should be done then the compound now designated oxophenarsine hydrochloride would become phenarsine oxide and the compound now designated dichlorophenarsine hydrochloride would become phenarsine chloride. Or these compounds also might be called oxophenarsine and chlorophenarsine respectively. If Dichlorophenarsine Hydrochloride and Oxophenarsine Hydrochloride are retained as U S P names, it appears not unlikely that the label will stress Dichlorophenarsine and Oxophenarsine with Hydrochloride appearing in smaller letters. Such a procedure it is understood by the Council, would be acceptable to the National Institute of Health and might offer some aid to the physician.

Dosage.—Initial dose 0.03 Gm for women and 0.04 Gm for men intravenously. The second dose may be increased to 0.04 Gm for women and 0.05 Gm for men. The maximum dose may be regarded as 0.05 Gm. Injection may be given every four to five days as it is excreted rapidly.

For children the initial dose should not exceed 0.0005 Gm (0.5 mg) per kilogram of body weight, the later doses should average between 0.0005 and 0.001 Gm (between 0.5 mg and 1.0 mg) per kilogram of body weight.

THE QUESTION OF INTRAUTERINE POLIOMYELITIS

Acute poliomyelitis complicating pregnancy is rare. McGoogan¹ collected 5 cases from the literature up to 1931, to which he added 3 additional cases observed in the state of Nebraska during the year 1931. Brahdý and Lenarsky² observed 3 instances of pregnancy complicated by poliomyelitis among 1,010 patients with poliomyelitis admitted to the Willard Parker Hospital during 1931. Among these patients were 30 over 19 years of age, of whom 15 were women, and 3 of these developed acute anterior poliomyelitis during pregnancy. Pregnancy and labor in these cases were not affected adversely. In no instance has a mother in whom poliomyelitis developed during pregnancy transmitted the disease to her offspring. Kleinberg and Horwitz³ present an analysis of 15 cases reported in the literature up to 1941, 1 personal communication and 13 cases which they collected. They conclude that pregnancy complicated by acute anterior poliomyelitis may be anticipated to progress normally, with a normal termination of labor and with normal offspring. The involuntary contractions of the uterus and the ability of the uterus to expel its contents spontaneously, observed also in patients paralyzed by cord tumors, spondylitis and vertebral fracture, are due to the fact that the uterus has an independent nerve supply and will contract not only after the spinal cord is transected but even after its sympathetic nerve supply is extirpated. There was no instance of intrauterine poliomyelitis in the 29 cases reviewed by them. The passive immunity of the offspring derived from the mother does not persist for long, since a number of cases of acute anterior poliomyelitis under the age of 1 month have

been reported. Lotti Hurny⁴ reports 1 pair of twins and another infant, all 3 full term, delivered by cesarean section from mothers with acute poliomyelitis. The infants were normal and remained so. Both women died a few days after the operation as the result of the ascending paralysis of the Landry type.

In this issue of THE JOURNAL appears a contribution by Harmon and Hoyne,⁵ in which the authors report 2 cases of pregnancy complicated by acute anterior poliomyelitis. Their second patient was admitted to the hospital four days after the onset of acute symptoms of poliomyelitis in her eighth month of pregnancy. Labor was induced and a normal viable child delivered. To date, ten months following birth, the child is progressing well and is apparently normal. There is no evidence of paralysis in the child. In their first patient symptoms of the disease developed in the sixth month of pregnancy. A spontaneous delivery of a stillborn fetus took place. The slightly macerated fetus had probably been dead for forty-eight hours or more. Postmortem examination of the child was carried out on the same day as the stillbirth. The spinal cord was removed and preserved in 50 per cent glycerin. Intracerebral inoculation of a *Macacus rhesus* monkey with the supernatant fluid from the ground emulsion of 0.3 Gm of the fetal spinal cord was performed after the preservation of the cord at 5 C for forty days in 50 per cent glycerin. The animal was observed for the ensuing twenty-six days and there were no consistent signs which might be attributable to poliomyelitic infection. On the twenty-sixth day the animal was killed and the cord removed for microscopic study. Sections prepared at four levels of the spinal cord failed to show any lesions characteristic of the disease. An attempted further passage of the latter material into a second monkey produced no symptoms.

There has not been an instance of the development of poliomyelitis in utero in the 34 cases reported. The 4 fetal fatalities in the Kleinberg and Horwitz series were due apparently to prematurity, to partial asphyxiation and probably to poliomyelitic toxemia. There is ample evidence, both clinical and experimental, that when a submicroscopic virus is present in the blood stream this virus can pass through the placenta and infect the fetus. This has been demonstrated for one of the viruses of encephalitis and for the viruses of measles, vaccinia, chickenpox and lymphocytic choriomeningitis. One of the properties of poliomyelitis virus is its ability to migrate along nerve fibers. Successful demonstration of virus in the blood of monkeys infected with poliomyelitis have been comparatively few, either because the virus is present in low concentration or

not at all. Gordon and Lennette¹ performed in monkeys repeated intranasal inoculation of virus after destruction of their olfactory bulbs. The inoculation did not result in a clinical attack of poliomyelitis, in the appearance of virus in the blood or in a detectable immunologic response. Apparently there was no absorption of virus by the blood stream. In the light of our present knowledge of the mode of spread of the virus of poliomyelitis, one may conclude that the failure of the disease to develop in the fetus of a mother with acute poliomyelitis is due to the low concentration of the virus in the blood stream or to its absence.

MALARIA

Most physicians during recent years have given little attention to malaria. Their attitudes have reflected the steadily diminishing incidence of indigenous malaria in the United States. However, circumstances associated with the war have checked this apathy and have brought a realization of the many problems which malaria still presents, particularly in the tropics. The experimental study of human infections has been retarded by the high host specificity of their parasites, thus has prevented transmission to laboratory animals. As a consequence analogous parasites of birds, and more recently of mammals, have been extensively utilized for laboratory studies. The value as well as the limitations of such parasites is exemplified by the work which led to Ross's fundamental discovery of the transmission of one species of avian parasite by a culicine mosquito and of his failure to infect mosquitoes of this group with human parasites. He did not achieve success in infection of mosquitoes with the human parasites until the "dapple winged" mosquitoes which we now recognize as anophelines were employed. The details of this relationship were later elucidated by Grassi. Thus, early in the experimental study of malaria the limitations of the interpretation of the human infection in terms of phenomena observed in the analogous infections of lower animals became manifest. Observations with apparent implications for human infections must always be confirmed with human parasites in the human host before their medical significance can be considered established.

An approach to the problems of malaria on more significant levels was opened when Warrington Yorke and S. P. James recognized that the malaria therapy of neurosyphilis, particularly that naturally induced by the employment of infected anophelines, offered many opportunities for investigation. A productive program has been sponsored for several years by the Florida State Board of Health and the Florida State Hospital with the financial support of the Rockefeller Foundation. Boyd and his associates have contributed mate-

rially to enlarge our knowledge of the malarias as self-limited infections.

Boyd² has shown that the white patients inoculated have not been a homogeneous group from the point of view of their susceptibility to vivax malaria. Those patients who experienced clinical attacks of from two to twelve weeks' duration, with a gradually declining parasitemia, are regarded as having been in a condition of pristine susceptibility at the time of inoculation. In these persons high densities of parasites prevail for some weeks after spontaneous subsidence of the paroxysms, the decline and disappearance of parasites is gradual. In a second group similar densities of parasites are attained at a similarly early period, and the paroxysms are of equal severity with those observed in the first groups, but after a period of clinical activity usually lasting not over two weeks the attack terminates abruptly coincident with a rapid and spontaneous decline in the parasitemia. Such patients evidently had an autochthonously acquired immunity to a heterologous strain of the vivax parasite, which soon becomes activated and capably deals with the new infection. In a third group the initial rise in the parasitemia is similarly checked, before clinical manifestations recur. Such patients have a potent immunity homologous to the strain employed in the induced inoculation. This homologous immunity may persist for several years, even in the apparent absence of a latent infection.³

The development of immunity is first manifested by the acquirement of a tolerance to the presence of the parasites. Whereas in the case of fully susceptible persons clinical activity is frequently initiated with densities of parasites of 10 per cubic millimeter or even lower,³ when clinical activity spontaneously ceases several weeks later densities of several thousand parasites per cubic millimeter still prevail. When the parasitemia finally disappears the defense mechanism has become fully activated, so that large numbers of homologous parasites may be rapidly removed if suddenly introduced.⁴

The demonstration that this acquired immunity is highly potent against the homologous parasites led to attempts at the hyperimmunization of convalescents by repeated reinoculations with the homologous parasite. Patients so treated apparently acquired an ability to remove promptly, without clinical reaction, doses of over 8 billion trophozoites introduced intravenously.

However, the transfer of 500 cc quantities of blood from such effectively hyperimmunized patients to a patient who had been inoculated with the homologous strain and another experiencing an active clinical attack from the same did not in the one case prevent a take or in the other produce any observable alteration in the course of the infection.¹

While vivax infections are usually benign and readily interrupted therapeutically, physician and patient are frequently perplexed by the recurrence of clinical activity after remissions of from six to eighteen months' duration.² Such recurrences are not observed in persons whose attack was induced by inoculation with infected blood³ or following natural inoculation when there has been no therapeutic interference with the evolution of the primary attack.⁷ Furthermore, the former infections are readily sterilized by a few small doses of plasmodicidal drugs⁵ while the latter, as already mentioned, frequently recur after repeated courses of treatment. Thus it would appear that the trophozoites are fully vulnerable to plasmodicidal drugs and are not present in situations inaccessible to drugs dissolved in the plasma. Since the clinical attacks following either method of inoculation appear essentially similar,⁶ it would appear likely that the variation is attributable to differences in the character of the inoculum, i. e. trophozoites vs. sporozoites. For many years Schaudinn's report of having observed sporozoites penetrate erythrocytes and transform into trophozoites was generally accepted. If this observation is true, the differences between artificially and naturally induced infections just described should not be expected. However, Schaudinn's report has not been confirmed. Further important points of difference between the infections resulting from the two methods of inoculation are that (a) by the administration of massive doses of trophozoites both the incubation and the prepatent period may be suppressed,⁸ while heavy doses of sporozoites will not effect a suppression of these intervals, (b) the blood is immediately infectious following inoculation by trophozoites,⁹ but following inoculation by sporozoites it appears to be free from parasites for nearly a week,¹⁰ and (c) available drugs are not reliable causal prophylactics, i. e., will not prevent the contraction of

infection from the bites of infected mosquitoes. These differences suggest that the sporozoites do not enter erythrocytes to become transformed into trophozoites and that there probably is an intermediate stage in the development of the parasite which is not passed in the erythrocytes. Exoerythrocytic stages are observed at various periods in the evolution of certain of the avian malaria infections. It seems not unlikely that something analogous occurs in the human infections induced by sporozoites and either that parasites in such a stage are protected from the drugs or that they are more resistant to parasiticidal drugs. When a new infection is interrupted by the early initiation of treatment shortly after the onset, not all the postulated intermediate stages have as yet completed their development and discharged their complement of trophozoites, belated parasites in this stage are not killed but perhaps are narcotized. It is likely that the induced remission will persist as long as the narcosis continues, but, if the effect is dissipated before immunity develops, further clinical activity is likely when the narcosis wears off and more trophozoites are produced. Until some drug is discovered which will attack the parasites while in this situation, the likelihood of vivax recurrences is probably enhanced rather than diminished by the early initiation of treatment.

ARTIFICIAL BLOOD GROUP A SPECIFIC ANTIGEN

Morgan¹ of the Lister Institute, London, has reported synthesis of an artificial antigen capable of stimulating the production of exceptionally high titer specific agglutinins and hemolysins for group A human erythrocytes.

About twenty-five years ago the theory of the production of antigens was broadened to include relatively simple organic compounds which in themselves are incapable of stimulating the in vivo production of specific antibodies. These are generally known as "partial antigens," "haptens" or "specificity determinants," since they can be raised to full antigenicity by conjugation with proteins or other colloidal "carriers." Thus combined they stimulate the in vivo production of polyvalent (or multiple) antibodies giving specific precipitation reactions with the resulting protein-hapten complex. One successful application of this technic is the conversion of bacterial polysaccharides into hapten-protein complexes which induce the formation of polysaccharide specific antibodies. Less well known is the preparation of successful antigenic conjugates with such complex haptens as agar and acacia.²

2 Partridge S. M. and Morgan W. T. J. *Chem Ind* 59 (1) 1940, *Brit J Exper Path* 23 84 (April) 1942.

The earlier haptén-protein conjugates were made by complex chemical processes. These were found to be inapplicable to many haptens since they led to partial or complete haptén denaturation. A more simple technique was therefore developed by the London biochemists involving the use of self-conjugating somatic proteins of the Shiga bacillus. A simple mixture of bacterial or vegetable polysaccharide with Shiga protein in saline solution often led to the formation of a stable polysaccharide-protein complex. The Shiga conjugates were found to be more highly antigenic than the earlier conjugates with relatively inert serum proteins. The Shiga complex is readily precipitated with the corresponding antiserum and gives positive complement fixation reactions and lethal anaphylaxis in haptén-sensitized guinea pigs.

The Shiga technique has been applied to the haptens which determine human blood grouping. Human blood group haptén A, for example, is present in commercial pepsin, in peptone and in hog gastric mucin. This haptén is a polysaccharide-amino acid compound which in itself does not stimulate the formation of anti A agglutinins in laboratory animals. Haptén A, however, is able to inhibit the agglutinating action of human anti A agglutinin on human group A erythrocytes in extremely small amounts. To raise this haptén to full antigenicity the gastric mucin polysaccharide and Shiga protein were mixed in the same saline solution and the reaction adjusted to pH 4.5 by the addition of acetic acid. The resulting precipitate was repeatedly washed by centrifugation. Rabbits whose tissues are free from A antigen were injected intravenously at three to four day intervals with the haptén-Shiga precipitate. From seven to nine days after the sixth intravenous injection antisera were drawn from these rabbits. These antisera would often agglutinate human group A erythrocytes in dilutions as high as 1:32,000. There was no agglutination in control tests with B or O group human erythrocytes. Positive reactions, however, were given at a somewhat lower titer with human A_2 , A_3 , A_1B , A_2B and A_3B erythrocytes. The anti A rabbit serum is strongly lytic for sheep erythrocytes in the presence of complement. This hemolysis is inhibited by the blood group A polysaccharide. Attempts at passive sensitization of guinea pigs were unsuccessful, presumably because of the presence of Forssman antigen in guinea pig tissues.

As a practical application of his results Morgan suggests the substitution of his high titer anti A rabbit antiserum for the human alpha agglutinin currently used. Such a substitution would lead to the ready detection of weakly reacting human erythrocytes such as A_2B , A_3 and A_3B , which are at present readily overlooked.

Attempts are now being made to prepare an equally potent anti B antiserum by conjugating B polysaccharide of human saliva with Shiga protein. The possibility of improving current antipneumococcus vaccines by a similar conjugation is also under investigation.

Current Comment

TOXICITY OF CHLORINATED HYDROCARBONS

Color compounds of the petroleum series have a wide use as degreasers of metal, cleansers of textiles, dry cleansers, solvents for rubber and other industrial uses. They are as a group not inflammable and have strong solvent properties. Hamilton¹ divides them into three groups: the saturated (paraffin) group such as methane and ethane, the unsaturated olefins such as ethylene and propylene and the naphthalenes. Methyl chloride, carbon tetrachloride, ethylene dichloride, acetylene tetrachloride and acetylene trichloride are industrially the most important. Tetrachlorethane, the common name for acetylene tetrachloride, is the most toxic of the chlorinated hydrocarbons that have been used in industry. All the substances, however, have some toxicity, Dr. Hamilton emphasizes that the increasing use of heat in connection with their industrial employment, as for example in degreasing with vapors of trichlorethylene or carbon tetrachloride, is far more dangerous than was the earlier method of dipping the material in cold fluid. If such vapors come in contact with a naked flame or with hot metal pipes, decomposition may take place with the formation of the highly toxic gas phosgene. Cases of poisoning with especially rapid development and great severity after brief exposure have most often arisen following the use of carbon tetrachloride fire extinguishers in a confined place. This summary of the toxicity of the chlorinated hydrocarbons parallels that by von Oettingen² of the aliphatic and aromatic hydrocarbons, including benzene and the more toxic benzene.

INDIVIDUAL SUSCEPTIBILITY TO DENTAL CARIES

The causes of dental caries remain obscure. In a recent study of this subject Gore³ concludes that the food impaction theory of Miller fails to explain individual susceptibility to caries and the mechanism by which the various types of decalcification of the enamel are produced. The chemical changes in the saliva following changes in diet seem to Gore to offer a more likely explanation. Salivary currents and the physical characteristics of the spontaneously precipitated mucin in the stagnant saliva, Gore says, play an important part in localizing to specific areas of the enamel the acid formed by hydrolysis and fermentation of the carbohydrate radical in mucin.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

DOCTOR SHORTAGE AND CIVILIAN HEALTH IN WARTIME

Following is a comprehensive report prepared by the Office of War Information. The data are secured from the United States Public Health Service, the War Manpower Commission and the Federal Works Agency

CIVILIAN HEALTH

1 Statistics of the Public Health Service show the lowest death rate on record, 10.3 per thousand, for 1942. The birth rate has risen from 18.7 per thousand in 1941 to 20.7 in 1942, and the maternal mortality rate has dropped for the thirteenth consecutive year and for 1942 was about 3 deaths per thousand live births. Infant mortality also continued to drop, falling 4 per thousand to 40 or 41 per thousand live births. The general death rate is a little less favorable so far this year.

2 Statistics on a sampling of workers, concerning sickness which caused absences of longer than eight days, show an increased number of man-days lost, especially from respiratory sickness. However, according to the Industrial Hygiene Division of the United States Public Health Service this increase is not greater than was expected from the strain of wartime living and working conditions.

3 The 1942 and more recent reports on communicable diseases, perhaps not the best gauge of adult health, show a mixed tendency. Influenza and typhoid, normally danger points under war conditions, were in 1942 below the peacetime average. Infantile paralysis and meningococcic meningitis (cerebrospinal fever) showed sharp increases this year. There have been flareups of smallpox and sporadic outbreaks of food poisoning and dysenteries. Strenuous efforts are being made to control the traditional wartime upturn of venereal diseases and tuberculosis deaths. The latter has not yet begun to show in health records.

SHORTAGE OF DOCTORS

The shortage of doctors for civilian practice will continue to increase indefinitely unless the requirements of the armed forces are revised. This arises, first, from the fact that the armed forces have commissioned to date only a little more than 80 per cent of their stated needs and are continuing to withdraw physicians from civilian practice, secondly, from the fact that 80 per cent of all new medical graduates will be commissioned.

There is no guaranty that a full 20 per cent of these graduates will remain for civilian work. Even if the 1,500 represented by this percentage should remain they would supply only about half the replacement needed in peacetime since, on the average, 2,500 to 3,000 doctors die annually.

Although it is logical to expect a greater number of deaths in war years from the strains of overwork, there is no evidence of this to date.

To compensate for this shortage the Public Health Service and the Procurement and Assignment Service of the War Manpower Commission are making all possible efforts to achieve the optimum distribution of the doctors remaining for civilian practice, to minimize needs by extensive preventive work and increase of medical care facilities.

These things are being accomplished by

1 Making surveys to show where needs are acute
2 Seeking to shift physicians from relatively well supplied areas to those where the ratio of doctors to population is substandard. As of August 1 a total of 1,469 doctors was reported relocated, 52 per cent to congested areas, dentists relocated totaled 72.

3 Limiting recruitment to twenty states and the District of Columbia, which are relatively well supplied, removal of physicians from substandard areas is minimized.

4 Helping local authorities to organize cooperative use of doctors and facilities for greater efficiency wherever consent can be obtained.

5 Improving and increasing hospital and clinical facilities. New facilities, largely financed under the Lanham act administered by the Federal Works Agency, include 44 health centers completed and 153 hospitals constructed or building. As of June 30, 1943 recommended hospital construction on 451 projects had been approved by the President.

6 Continuing attempts to improve sanitary conditions (300 water supply projects at a total cost of \$81,000,000 finished in congested areas under the Federal Works Agency) and by Public Health Service emergency work in control of diseases (700 additional professional and more than 3,000 nonprofessional personnel assigned to local health department work, malaria control, endemic typhus, industrial hygiene and so on).

7 Extensive work to control the spread of venereal diseases by breaking up districts of prostitution near industrial and military centers, by army prophylaxis work, by establishing treatment centers where infected women can be cured of syphilis and gonorrhea through the new rapid treatment techniques and an attempt made to rehabilitate them.

8 Widespread case finding work in tuberculosis through the new inexpensive x-ray traveling units set up by the Public Health Service under Dr. Herman E. Hilleboe, capable of checking on 20,000 persons a week.

Dr. Thomas Parran, Surgeon General of the United States Public Health Service, estimates on the basis of surveys made by his field units, in cooperation with the Procurement and Assignment Service of the War Manpower Commission, that 332 known localities will need about 500 doctors and dentists in the next fourteen months. However, he adds that such needs actually become acute long before they find their way into formal reports.

Dr. Joseph W. Mountin, Assistant Surgeon General, summarizes the overall statistical picture this way: "There was a pre-war registry of 180,000 registered physicians listed in the United States. Of these, 15,000 were full time employees of public health agencies, medical schools, insurance companies, etc., 28,000 were more than 65 years old and evaluated as only one third effective, 7,000 under 65 were completely or partially ineffective, 3,000 were residents in hospitals, and 42,000 were in the armed forces, as of Jan 1, 1943." These figures show, as of the first of this year, 95,000 fully effective doctors available for civilian practice, plus a percentage of service from some 32,000 others partly incapacitated by reason of age or other factors.

During 1943, 11,000 of the 95,000 fully effective doctors were to be taken into the armed services, making a total of 53,000 physicians allotted to the care of sickness and injuries for an army estimated at 10,800,000 men when fully enlisted. This leaves 84,000 physicians, surgeons, specialists and general practitioners—plus 15,000 public health doctors, plus 5,000 interns and 3,000 residents, a total of 108,000, to care for the nation's remaining 120,800,000 civilians. These are the figures of the Procurement and Assignment Service.

It is estimated that, assuming perfect distribution, there would thus be 1 effective doctor for every 1,118 persons or, in general practice, a ratio of 1 to 1,557. This is very close to the ratio of 1 to 1,500 "considered desirable from the standpoint

of health protection" But perfect distribution does not exist for many reasons and, short of compulsory shifts of doctors to critical localities, is not attainable

Dr Mountain has stated that "in general no military or industrial community should have less than a ratio of 1 physician to 3000 population if its citizens are to have even a fair standard of care" However, the end point of the induction of civilian doctors into the armed services is in sight The Army and Navy training program, when it becomes fully effective in 1944, will take care of all further needs for professional personnel The first full class will be available in September 1944

If this were the complete picture, relocation of doctors and other remedial measures might be expected eventually to rectify the situation But another factor operates to cause a continuing and increasing shortage of doctors This is the ordinary attrition of death which, even in peacetime, removes between 2500 and 3000 doctors annually from their practice It is expected that wartime strains, overwork and the return to practice of overage and retired physicians will increase this annual loss Replacements will not be available unless there is an alteration of the plan to induct 80 per cent of new medical graduates into the armed forces These number about 5,000 every nine months because of the speeded up schedule for training, or an average of 7000 a year Of these it is estimated there would be only 1,500 to replace the 2,500 to 3,000 doctors who die yearly

Everything possible is being done to assure the best possible distribution of the remaining physicians Doctors are to be taken into the armed services only from those twenty states, plus the District of Columbia, which show the most favorable ratio between doctors and population None are to be taken from fifteen specified states in which influx of workers has made shortage of medical care critical States from which doctors are not to be taken are Alabama Arizona Delaware, Georgia, Idaho, Kentucky, Louisiana, Mississippi, New Mexico, North Carolina, South Carolina, Tennessee, Texas West Virginia and Wyoming

Dr Frank H Lahey, chairman of the Directing Board, Procurement and Assignment Service, has reported a total of 1,469 doctors and 72 dentists relocated Some of the shifts of doctors from one locality to another were arranged by the commission, others resulted from work by other agencies, and still others were unsolicited movements Of these, 389 were relocated in the states listed which have an unfavorable doctor to population ratio Alabama reported 76, Arizona 27, Georgia 17, Idaho 2, Kentucky 93, New Mexico 2, North Carolina 7, South Carolina 23, Tennessee 39, Texas 87, West Virginia 13, Wyoming 3 Of the 1,469 doctors, 604 were relocated before January 1 An examination of the records on these showed 52 per cent moved into congested areas of the type in which doctor shortages have chiefly developed Twenty per cent went into towns with populations between 5,000 and 25,000 Comparison with the joint surveys made by the United States Public Health Service and the Procurement and Assignment Service of the War Manpower Commission shows that among those communities where shortages were found 24.4 per cent have received at least one additional doctor

One of the basic problems of relocations is the difficulty of licensure Of the 604 doctors checked, 154 had crossed the state line barrier and, in a majority of cases this entailed taking a new medical examination These ordinarily are given only once or twice a year, but some states recognizing the critical nature of the problem, have given as many as six Only seven states have laws permitting temporary licensure These are Delaware, Maine Nevada Pennsylvania Washington, New York and Montana One state, Florida, permits out of state doctors to practice there under supervision of the state medical director of civilian defense Procurement and Assignment estimates that nineteen other states have laws making a similar arrangement possible but Florida alone is exercising the privilege

Recently the War Manpower Commission's Procurement and Assignment Service endeavored to place some foreign doctors who have been licensed by the state of New York These doctors had not yet been in this country long enough to become citizens but all had their first papers The service found that

the states had medical license reciprocity with New York but none of these states could by law, admit the foreign doctors Four of these nine states require that doctors be citizens, the laws of another group of four forbid acceptance of graduates of foreign schools the ninth requires that graduates of foreign schools have further education in the United States

Analysis of state licensure requirements, as applied to foreign doctors and listed by the State Board Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for 1942, shows that twenty eight states require full citizenship as a preliminary to practice and fourteen require first papers only Those requiring full citizenship are Alabama, Arkansas, Delaware, Georgia, Idaho, Iowa, Kansas, Kentucky, Maine Michigan, Minnesota, Mississippi, Missouri Montana, Nebraska, New Hampshire, New Jersey, North Carolina North Dakota, Ohio, Oklahoma, South Carolina, Texas, Utah, Vermont, Virginia, West Virginia and Wyoming plus Alaska, Hawaii and Puerto Rico Those requiring only first papers are Colorado, Connecticut, Illinois, Louisiana, Maryland, Massachusetts, Nevada, New Mexico, New York Pennsylvania, Rhode Island, South Dakota, Washington and Wisconsin However, of those states that require only first papers, Louisiana withholds permanent license until citizenship is completed Many states exempt Canadians from these requirements

Many other states will not accept doctors who do not have American medical degrees, and these include Arizona, Arkansas, Colorado Illinois, Kansas, Kentucky, Maryland Minnesota, Mississippi, Nevada New Hampshire, New Mexico, North Carolina, North Dakota, Oklahoma, Pennsylvania, South Carolina, South Dakota, Tennessee, Utah, Washington, West Virginia Wisconsin and Hawaii

This pool of foreign doctors is estimated to contain 6000 variously qualified physicians According to figures given by Harry D Beale of the National Center for Resettlement of Foreign Physicians, 2000 of these men have become United States citizens and many of them, who have taken out only first papers, have been licensed to practice medicine in this country Between 3000 and 3500 have been licensed in New York, 400 in Massachusetts 150 in Ohio, 250 in California, 250 in New Jersey 100 in Connecticut and 100 in Maryland Only 50 of these men have been taken into the Army, which has stringent regulations about their employment Doctors taken into the Army must be American citizens and must undergo rigid scrutiny for reasons of security

Seven or eight foreign doctors are being used in California, which, previous to the present crisis had set up a physicians' service, sponsored by the state medical association, to care for migrant farm workers who flooded the state during the dust bowl era This service now has shifted its attention to the federal projects housing industrial workers

It was pointed out that these foreign doctors constitute our largest available reserve of physicians and that, in another respect they fit well into the present medical care crisis Officials estimate that fully half of these doctors will return to Europe after the war and thus, if they fill in where current needs are acute will not remain after the war to displace men returning from the armed services

The ease or difficulty with which out of state doctors are admitted to practice depends largely on local licensure Where the need is recognized, ways are found to permit doctors to enter and relieve the critical shortages which government surveys have shown to exist Occasionally local physicians not realizing the need, have not cooperated However this situation seems to be changing, and there have been a number of cases of doctors and medical associations reversing their previous opposition on condition that those doctors who enter their bailiwick do so only for the duration of the war

It is stated that of the 45000 or more doctors inducted into the armed services 1500 have been released to civilian practice again and presumably must be replaced Three hundred were discharged between January 1941 and April 1942 Since that time and up until May 1943 1200 others had been released

Letters were written to 200 of these doctors in an effort to determine whether any were available for relocation Of those who replied by far the major portion had returned to their original practice and only 2 per cent indicated they were

willing to shift to a different locality. Some of them were incapacitated physically, but most were perfectly capable of carrying on civilian practice.

HEALTH FACILITIES

Another attack being made on the problem of decreased medical care for the civilian population is an extensive enlargement of hospital and sanitation facilities. Most of these are financed under the Lanham act by the Federal Works Agency. As of July 31, 1943 the FWA lists 33 new hospitals as wholly or substantially completed at an estimated cost of \$4,265,513, of which the government allotted \$3,481,435. These 33 hospitals will supply an additional 1,615 beds for civilian care. Those hospitals for which funds have been allotted—including some under construction, some on which contracts have been awarded and some on which bids have been asked—total 250 and will cost \$53,451,136, of which the government is paying \$44,702,052. These hospitals will supply an additional 13,827 beds for civilian care. Health centers are smaller projects, usually providing clinics and sometimes 6 to 8 emergency beds. Construction of these projects is financed with federal and local funds and operation is by local authorities. Of such projects 44 had been completed as of June 15, 1943. Other projects financed through the Federal Works Agency as War Public Works and Services, including a great number already finished, and others approved by the President, as of June 30, 1943, include those listed in table 1.

TABLE 1—War Public Works and Services

Type of Project	Number of Projects	Estimated Total Cost	Federal Funds
Total *	3,874	\$431,109,070	\$302,979,098
Schools †	1,883	162,298,630	77,818,220
Medical (hospitals, venereal disease hospitals and health centers)	489	72,385,054	62,845,973
Water	305	83,086,215	69,303,301
Sewerage sanitation	293	47,975,331	40,802,529
Recreation	692	30,092,941	29,036,402
Power	10	20,515,599	12,019,716
Fire, police	123	3,877,635	3,144,295
Streets, highways	37	3,880,143	3,051,807
Other ‡	42	6,998,122	4,350,855

* Includes \$26,144,470 transferred by warrant to agencies outside FWA as follows: (A) WPW schools, 37 \$6,791,432; medical, 1 \$151,000; water \$75,160; recreation, 209, \$18,160,728; and fire and police, 3, \$28,220; and (B) WPS \$267,850.
† Includes nursery schools and child care facilities.
‡ Garbage disposal, miscellaneous utilities and so on.

A further report from the Public Health Service shows that the PHS has recommended 451 health centers and hospital projects, through surveys made by its reconnaissance units. As of Feb. 15, 1943, 358 had been recommended and approved, and 153 had been constructed or were building.

The Federal Works Agency, under the Lanham act, also finances an extensive child care program and rehabilitation work in venereal disease rapid treatment centers under the direction of Miss Florence Ken.

Other government agencies are also making a vigorous attack on the problem of shortages. In areas where army camps have many civilian workers and where local medical facilities and doctors are lacking, the Army may request that the section be declared a "remote area." If this is done, the civilian workers may receive care through military facilities on a fee basis. The Army has pending, at present, requests to have ten such areas declared remote. In one such area, civilian employees number more than 7,000 and have no health protection other than could be provided in this way.

Medical care is reaching out into the sea lanes also, and for the first time in history merchant seamen will have health facilities aboard ship. Today pharmacist's mates are being assigned to merchant vessels carrying cargo to battle lines all over the world. In addition, merchant seamen suffering the strains of enemy attack—war neurosis or combat fatigue—are being treated and rehabilitated through a program sponsored by the War Shipping Administration and the Public Health Service.

In the volunteer civilian services, additional work to relieve shortages also is being done. The Red Cross nurse's aide pro-

gram, which seeks only to take the strain off graduate nurses by performing minor parts of their tasks, has a total of 85,679 such volunteer workers who have completed the required courses. The last survey showed that during a period of a month about 80 per cent of the trained workers were active. Maximum cooperation of the volunteer workers was obtained, according to the Red Cross, where the hospitals made a serious effort to work the volunteers into their routine.

TABLE 2—Joint Survey of Pascagoula, Miss., Made on Jan. 5, 1943

Population of Pascagoula and Moss Point area in 1940	9,000
Population at time of survey	10,000
Number of practicing physicians in area in 1940	9
Number of effective practicing physicians at time of survey, including one over 70 years of age	8
Ratio of physicians to population in 1940	1 to 1,000
Ratio of physicians to population at time of survey	1 to 1,250

HEALTH SURVEYS

No program of stretching health facilities and medical care could operate efficiently without fact finding surveys. The Public Health Service, in cooperation with the Procurement and Assignment Service of the War Manpower Commission and local authorities, is conducting continuous investigations in congested areas to determine their precise needs.

On March 1, 1943, according to the Public Health Service, joint studies had been made of thirty-three communities in sixteen states. The investigating agencies are unanimously agreed that there is urgent need in twenty of these communities for additional medical, dental and nursing personnel. Such surveys are made whenever local authorities or federal agencies direct attention to community problems and are carried forward as rapidly as the number of workers will permit.

Two such surveys are summarized in tables 2 and 3.

The Pascagoula and Moss Point region is a vital war area the population of which is mainly employed in shipbuilding. It is estimated that by June 1943 the population will be 42,000 because of completion of new housing projects. Local and federal surveyors agreed that 4 additional physicians were urgently needed if suffering and actual loss of life are to be avoided. The ratio of physicians to population was put at approximately 1 to 3,500 in June 1943. By March 1, 1943 state and local groups had induced 2 additional physicians to locate in Pascagoula.

Orange County has three important shipyards, working on a twenty-four hour basis. The estimated population of war housing projects is 27,260. The survey group agreed that 2 additional physicians and 1 dentist should locate in Orange. The report recommends that 1 additional physician trained in public health be assigned to the Orange Health Center. It was also recommended that the 3 doctors employed at the Consolidated Steel Company yards obtain authorization to enter into private practice during their off hours.

TABLE 3—Joint Study of Orange County, Texas Made on Feb. 22, 1943

Population of Orange county, 1940	17,000
Population of Orange county, February 1943	6,000
Number of physicians, 1940	9
Number of practicing physicians, February 1943	3
Ratio of physicians to population, 1940	1 to 1,889
Ratio of practicing physicians to population, February 1943	1 to 2,000

Reports on other surveys by these same services were made available to the Office of War Information. Names of localities are withheld because the reports are confidential and the instances given are used as samples rather than specific cases. Abstracts follow.

In one Southern seacoast city, as the result of an influx of workers for war work the population has increased from 27,000 to an estimated 70,000 in three years. The survey showed that this area has only 14 effective physicians and 4 dentists. Each doctor had 20 to 40 patients daily at his offices and was able to make only 3 or 4 home calls a week. There are no

of people rising from the sick bed dressing and going to a doctor's office to wait several hours for treatment. Some doctors refused night calls, others sent emergency cases to the hospital where there was no intern and where it would be necessary for the patient to wait until a doctor could go there. It was necessary to wait three and a half to four months for a dental appointment. This survey showed that there was still a housing shortage, that there was an inadequate number of food stores, that restaurants were not only few but overcrowded and poor and that laundry services were inadequate. Under these conditions the survey group was not surprised to find that daily absenteeism at the war factories ran as high as 11 to 16 per cent and that the labor turnover was extremely heavy. There was a record that of 818 employees hired by one concern 566 either had been fired or had left the company's employ.

The surveyors held the threat of epidemic to be serious not only that there was danger of epidemic in such crowded and below standard conditions but that should an epidemic break out, the doctors would be totally unable to cope with the situation both because of their small numbers and because of the inadequacy of hospital facilities.

The only hospital for this community of 70,000 persons contained 68 beds, of which 18 were reserved (in the basement) for Negroes. Since Negro doctors were not allowed to use hospital facilities these beds were not often filled. On July 1 a new wing was started for this hospital, which will contain 30 beds when completed. Nurses quarters are to be built thus releasing 35 more beds in the hospital proper.

As a result of the survey the shipyards hired a physician and assigned him to a housing project as a practitioner. The doctor in charge at the shipyard wishes to hire 3 more. The survey also succeeded in having a community council set up to handle the problem. An intern was hired for the hospital. An army doctor nearby, whose duties required only about one hour daily, has sought permission to help.

Another survey was made in January 1943 of an Alabama community whose population in three years had jumped from 13,171 to an estimated 25,000 plus an estimated 10,000 additional newcomers in the county. 11,800 workers are employed making munitions. To take care of this population there are 10 effective white doctors. No hospital is available for Negroes, who comprise 26 per cent of the population. In the county there are 4 effective doctors though 7 practice there. Four doctors were taken from this community by the armed services and 3 others have died. No new doctors have entered. The picture resolves itself into 21 effective doctors making a ratio of 1:3,800 far above the critical ratio of 1:3,000 and more than double the desirable ratio of 1:1,500. Another hospital is urgently needed, as well as 2 to 7 new doctors, 1 of whom should be an obstetrician.

In a survey of another Southern community made at approximately the same time an even more serious situation was found. This community, a county which included three towns showed an increase of population from 51,842 to about 75,000 within three years. (Estimates of increased population are approximately accurate, being based chiefly on the issuance of ration books.) The population of one town had increased 200 per cent, another more than 100 per cent and a third had risen from 515 persons to 5,000. There are two ordnance plants in the county employing 15,000 persons. The ratio of doctors to population in the county is 1:3,600. Two doctors have been taken by the armed services. The ordnance plants have a total of 10 or 11 doctors who do not practice in the community. One of the towns in this county has a new health center with 6 beds and almost enough equipment for obstetrics and general surgery. There has been some discussion of its use as a maternity center but nothing has been done. An allotment of \$106,000 has been approved for an 80 bed hospital with quarters for 22 nurses. Recommendations were made that the hospital construction be hurried that the ordnance plant doctors be made available for emergency use that there be no further drafting of doctors from this community that the health center be used as a maternity center that funds be found for its equipment from federal sources that public health nurse services help the doctors and that 2 doctors at least 1 a Negro be sent to the community.

Norfolk Va and its sister cities about Hampton Roads form one of the critical areas of the Eastern Seaboard. Here a large new water supply has been brought in financed under the Federal Works Agency, and approval of priorities is sought for a new privately financed hospital. The population has risen from 251,318 to an estimated 460,260. The survey shows that 15 doctors are needed as well as 16 dentists and 5 public health nurses. In Norfolk the doctors and the medical association will welcome assistance and new doctors, but the reaction of physicians in other localities is by no means uniform. In one area doctors opposed the building of a health center because they said, it pointed the way toward 'socialization of medicine'. They also opposed free immunization of industrial workers by public health officials, saying that the workers were simply able to pay for injections vaccination and so on.

In a Southern seaport and shipbuilding center a resurvey is in progress. Here the doctors formerly were opposed to the introduction of any new physicians unless they were uniformed men sent in temporarily and resisted any idea of liberalizing the licensing system. If a state health officer asked for uniformed doctors the Public Health Service would be unable to supply them because it does not have sufficient funds for the purpose.

PREVENTION

Another extensive phase of the fight to preserve civilian health falls in the division of prevention professional and popular education in public health methods maintenance of healthful and sanitary conditions and work to arrest the spread of preventable diseases.

Industrial—The Public Health Service's Division of Industrial Hygiene operating through thirty-eight state and eight local bureaus has one of the largest single undertakings in civilian health. It has direct and indirect supervision over the working and living conditions of an estimated 30,000,000 workers. This force is divided 22,000,000 working on arms, ship building munitions and construction and 8,000,000 on transportation public utilities food processing and farms. The Industrial Hygiene Division's work was intensified by the fact that up until 1943 73 per cent of war contracts had been awarded to factories in twenty big centers which had 22 per cent of the total population of the country. A further complication was the construction of war plants in rural communities which lacked even rudimentary sanitary facilities and the fact that the ranks of state and local public health workers were depleted showing a shortage as of February 1942 of 1,000 doctors and 2,700 public health nurses.

The Division of Industrial Hygiene increased its workers to 300 and gave special training to 60. Through this force the division in cooperation with local and state authorities maintains almost constant surveys of factory health conditions keeps up continuous laboratory work for elimination of industrial hazards sponsors educational campaigns on hygiene and nutrition and keeps continually before management the advantages of having medical supervision in their shops.

The latest available survey of industrial hygiene services in plants employing almost a million and a half workers showed as of 1939 that 15.1 per cent of the workers were supplied with hospital facilities 15.5 with full time doctors 33 1/3 with full time nurses and 47.5 with a trained first aid worker. Because of the huge influx of new workers these figures may have fallen off slightly. However there was an increase of 10 per cent last year in industrial employment of public health nurses and also a definite increase in interest among physicians and communities in industrial hygiene. Many institutes (four or five day series of lectures) have been held throughout the country to establish what the Public Health Service refers to as the framework of industrial hygiene. This framework which the national service urges on state and local authorities places strong emphasis on preplacement examination not only to put every available man and woman to work but also for the purpose of placing handicapped or less sound workers in those jobs for which they are best suited. Other features of the framework stress the medical setup in the plant, ventilation over machine safeguards ventilation and heating sanitation and recreation facilities and better health in the homes including recreation and housing. It was estimated that

connection that 90 per cent of all sickness absences are caused by nonindustrial sickness and accident.

In addition to plant surveys by local and state officials, federal workers make frequent field trips. The Public Health Service is directly responsible with the Surgeon General of the Army for supervision in government-owned industry, its work in other fields is on the basis of requests from management or labor in industry or of cooperation with local health authorities. These field trips have covered many industrial factory setups but also many where the most rudimentary safeguards for workers' health did not exist. In a factory which made rubber rafts for planes, a field worker found a turnover of 25 per cent in employees in one particular section where cement was brushed on seams. The odor of the chemicals used was stifling, and it was clear that headaches and similar ill results from the fumes were unavoidable. The factory had provided the required exhaust ventilation sucking out the fumes through a grid which also formed the work bench on which the chemicals were spread on the rubber. It had neglected to teach the workers that, in spreading the chemical they must not put it on the grid. Consequently the grid was clogged and the ventilation system was not functioning properly.

In another factory, where bullets were made, the machinery was old, ill lighted, and without the most elementary safeguards. On the other hand, this factory employed a full time public health nurse who was doing splendid work. This woman had returned to her home town with a sense of mission and had sold her services to the factory on a part time basis, the understanding being that she would work half time on the assembly line. After two months of this work the management realized the value of her work and put her on a full time basis as a nurse. A factory whose workmen became caked with dust provided only pails of water for them to wash in at quitting time. A West Coast shipyard, whose payroll had increased from 500 to 5,000 men, had provided no additional toilet facilities and no additional sewage disposal. The water supply was contaminated and several hundred cases of dysentery occurred before the condition was corrected. It was emphasized that these cases were by no means typical of all factories, but that they did represent a measurable percentage of those inspected.

Tuberculosis—The work of detecting tuberculosis in its early stages is considered extremely important. According to Surgeon General Parran the death rate from tuberculosis increased 13 per cent in Great Britain after two years of war. There has been no increase here as yet, but the objective circumstances favoring such an increase are prevalent. These include overcrowding and longer hours of work, with resulting fatigue and emotional strain.

Educational work to encourage proper eating, personal hygiene and rest is being done by the Public Health Service, chiefly by distribution of literature and consultation or organizational work with local and state health authorities. But the main reliance is placed on x-ray diagnosis. To this end the Office of Tuberculosis Control was set up under Dr. Hilleboe. Ten portable x-ray units were obtained and set up in trailer-automobile units, staffed with three workers, a doctor, an x-ray technician and a clerk. The cost of the x-ray units is about \$5,000, of the trailer \$1,200. With these units, in cooperation with industry in congested areas, a quarter of a million persons were x-rayed in 1942. These include 160,000 workers in nine states and 40,000 federal employees in the District of Columbia. An additional ten units were purchased, but failure to obtain an expanded appropriation for this year's work permitted the Public Health Service to place only two of these in operation. Two are being held in reserve and the remaining six will be lent to states where they will have the maximum utility. Dr. Hilleboe expects by these units to x-ray a million persons this year at a unit cost of about 15 cents per examination, and he has requests for work which would include another million whom he is unable to examine because of lack of funds. The present rate of work for each mobile unit is about 2,000 x-ray examinations a week. These units utilize an inexpensive microfilm technique and new equipment which permits taking as many as 300 to 500 photo-fluorograms in a normal eight hour day.

Veneral Diseases—Another of the danger points in communicable disease where prevention plays an important role is syphilis and gonorrhea. A rise in venereal diseases traditionally accompanies war, and England has experienced an increase of 70 per cent. In this country an increase of 20 per cent in patients treated at public clinics has already occurred. The Public Health Service conjectures that a great portion of this apparent rise may be due to an increase in serologic tests and augment case finding throughout the country. It is estimated that 30,000,000 such tests will be made in 1943. Districts of prostitution have been closed in three hundred communities, and it has been found necessary in only two areas to invoke the stringent May Act, which makes prostitution a federal offense in districts designated by the Secretaries of the Navy and of War. The two areas include twenty-seven counties in Tennessee and twelve counties in North Carolina. Venereal clinics have been increased by 300 per cent since 1938. Nearly 10,600,000 syphilis treatments were given last year by public health doctors, an increase of 260 per cent over 1938.

A further extensive work to curb venereal infection is going forward swiftly, financed jointly by the Lanham act and Public Health Service funds. Rapid treatment centers have been established for the treatment and rehabilitation of infected prostitutes. Twenty-nine such centers have been opened in fifteen states, Puerto Rico, the Virgin Islands, the District of Columbia and the Canal Zone. Eleven more centers have been approved, six others recommended and awaiting approval, and twenty are being considered. The twenty-nine centers already functioning have a capacity of 3,400 beds and are kept constantly supplied with patients through arrests and commitments by state and local officers. Turnover is on an approximate maximum basis of six weeks per patient. Treatment is primarily by the new intensive methods for syphilis and the use of sulfonamide drugs for gonorrhea. These faster methods of treating syphilis vary in length from one day to six weeks. Intensive treatment is said to give great promise and may supplant the classic treatment which required some seventy injections spread over a period of eighteen months or more. Sulfonamide drugs permit a cure of 80 to 90 per cent of gonorrhea patients in a week's time. In addition to health treatments, extensive educational and rehabilitative work is done at these centers, and it is hoped that many of the girls and women will find their way into more normal life through wartime jobs.

Typhus—Despite preventive work, typhus, spread in this country by the rat flea, was continuing to increase in 1942 when 3,700 cases were reported, a rise of 1,000 over the previous year. It is believed that the actual incidence of the disease is several times as great as the number of cases reported. Typhus has been gradually spreading northward along the East Coast and along the granary lines in the Middle West. The principal foci of infection are in Texas and Georgia. The way to stamp out typhus is to kill its host, the rat. Buildings in centers of infection are being rat proofed and the rats destroyed. A district at a time, whenever local authorities will assume responsibility for continuing the work. The Public Health Service has set up a field office for typhus control with headquarters in Atlanta. A field officer carrying out control work reported 231 rats killed by a single fumigation in one small grocery, plus an uncounted number of others gassed in their burrows. Twelve persons employed in that store had been infected with typhus in the two previous years.

Malaria—Extensive work in malaria control has been done in the last two years, and \$6,000,000 is to be spent on such work in the coming year. Today a protected zone is being created around every war industry and every military camp in the malaria belt. These projects have employed 3,700 men to protect 1,161 war establishments in eighteen states. As an index of the effectiveness of this work, the Army experienced its lowest malaria rate in its history in continental United States, 0.6 per thousand men in 1942. So far this year the rate is 0.7. Considerable work is being done also in the Western states in control of bubonic plague, which is endemic there among wild rodents. Areas surrounding military camps are cleared up, and there is a continual sampling of rats in urban communities.

the West Coast. In the last year plague was found among rats in two communities—one on Puget Sound the other near San Francisco. Immediate action to exterminate rats resulted in cleaning up the areas, and recent examinations have shown no traces of the plague.

Diseases from other parts of the world unknown in this country are being guarded against also. Such exotic diseases may gain a foothold unless preventive measures are taken. Global warfare, which breaks down national barriers and makes worldwide communication easy, also opens a path for invading disease germs via plane and ocean vessel passengers and returning troop. Two examples of such exotic diseases—not yet successful invaders—are filariasis, a disease of the lymph glands transmitted by mosquitoes, and schistosomiasis, an intestinal

infection prevalent in Africa Central and North America and the West Indies, transmitted by snails. Mosquitoes and snails of the United States therefore are being studied to determine whether they might become carriers of these possible invaders.

Because of the possibility of aircraft transporting insect carriers of plague, yellow fever, typhus and other infectious diseases, all planes from foreign ports are fumigated twice—once before arrival by flight personnel and on arrival by the Public Health Service. New ocean vessels constructed for our wartime merchant marine incorporate Public Health Service ratproofing specifications. Ratproofing, incidentally, saves money and time. It saves steel during construction and saves dollars and hours after construction owing to the fact that ratproofed ships seldom require fumigation.

NAVY

MEDICAL FIELD PHOTOGRAPHIC UNITS

The Secretary of the Navy, Frank Knox, has authorized the Bureau of Medicine and Surgery to organize and equip two medical field photographic units for the purpose of obtaining documentary clinical photographic records of the medical and surgical management of naval casualties in the combat areas. One unit will be assigned to the Pacific area, the other to the Atlantic European area.

The fundamental plan is to secure a coordinated series of motion and still pictures illustrating war injuries using individual case histories as far as practicable and following them from the field of combat along the chain of evacuation to final destination. In addition to case history reports, a photographic record will be made of environmental conditions wherever pertinent and necessary so as to familiarize medical personnel with the problems to be encountered. In addition to war casualties the units will be concerned with disease problems, particularly tropical diseases.

The Division of Preventive Medicine, which will have direct cognizance of this work, will appreciate comments and suggestions from officers in the bureau as to suitable material and locations for such medical field photography.

LIEUT. COMDR. CHARLES E. BALDREE, JR. CITED

Lieut. Comdr. Charles E. Baldree, Jr. (MC), U. S. N. R. formerly of Belleville, Ill., has been cited for splendid service to wounded Americans evacuated to his ship. The citation came from Lieut. Gen. S. B. Buckner, Jr., who is commanding general of all U. S. forces in the Alaska area where Dr. Baldree is stationed. The citation reads as follows:

Reports have reached me from several sources concerning the splendid service rendered by you to U. S. Army troops wounded at Attu and evacuated to your ship. Your untiring efforts and professional skill greatly alleviated the suffering of our troops during their trying voyage.

I wish to convey my appreciation of your magnificent work and trust we may be so fortunate as to have the benefit of your services again in this theater.

Dr. Baldree, who graduated from the University of Tennessee College of Medicine in 1928, entered military service in August 1942.

NAVY CROSS AWARDED TO DR. RINGNESS

Lieut. Henry R. Ringness (MC), U. S. Navy, has been awarded the Navy Cross posthumously for extraordinary heroism while under fire on Guadalcanal. Lieutenant Ringness, who died of wounds sustained in the action in which he earned his decoration, graduated from George Washington University School of Medicine, Washington, D. C., in 1939. The citation accompanying Lieutenant Ringness's award is as follows: For extraordinary heroism as flight surgeon of a marine aircraft group during action against enemy Japanese forces on Guadal-

canal on the night of Oct. 13-14, 1942. When a hostile task force moved in off our beachhead and commenced a vigorous bombardment of the island airfield, Lieutenant Ringness, trapped in a foxhole in the camp area by the sporadic bursting of shells, was mortally wounded by a near miss which killed four of his companions and wounded others. Although completely paralyzed in the lower half of his body and suffering great pain because of his immobility, he persisted in administering morphine and blood plasma to wounded personnel until he was finally evacuated to a base hospital. Even then, with unselfish devotion to his fellow man, he tried to minimize his own critical condition in order that others might be given preference in medical treatment. Three days later, as a result of his injuries, he gallantly gave up his life in performance of duty in service to his country.

WOMEN OFFICERS' UNIFORMS

According to the *Army and Navy Journal* of September 4, women physicians commissioned for service in the Medical Corps of the Navy or any other women in the U. S. Naval Reserve who may be appointed as officers in Navy staff corps will wear the basic uniform originally adopted for the Women's Reserve, U. S. Naval Reserve. The special types of staff corps service will be indicated by the appropriate corps insignia worn above the sleeve stripe and when the uniform jacket is removed by the miniature collar device.

The staff corps device shall be of the same color as the sleeve stripes prescribed for the navy women's uniform—reserve blue on the navy blue uniform and navy blue on the white uniform. The acorn, where used on staff corps insignia, will be embroidered in appropriate contrasting color of either white or reserve blue.

In addition to the medical corps, women are now serving in the hospital corps, supply corps and civil engineer corps and will wear the appropriate corps devices.

NAVY PERSONALS

Capt. Robert P. Parsons (MC), U. S. Navy, who has recently returned from command of a naval hospital in the South Pacific area, has been assigned to command a new naval hospital at Pleasanton, Calif., which will be completed on October 1.

Comdr. Richard I. S. Silvis, U. S. Navy, has been appointed medical officer at the air station's Naval Air Technical Training Center, succeeding Comdr. M. I. Tendler. Commander Silvis reported to the training center after sixteen months of sea duty aboard the U. S. S. *Charrier*, an auxiliary aircraft carrier. He has been in the regular navy since his graduation from the University of Nebraska College of Medicine, Omaha, in 1931.

Lieut. Col. James E. Peterman, M. C. A. U. S., formerly district health officer with the Pennsylvania Department of Health, has recently been transferred from the office of the Surgeon General, Washington, D. C., to foreign service where he will serve as vital statistician for one of our overseas forces.

MISCELLANEOUS

MORE REGISTERED NURSES NEEDED

The Directing Board of the War Manpower Commission's Procurement and Assignment Service announced on September 1 that the nation is faced with a critical shortage of registered nurses. More than one fifth of all the active nurses in the country are with the armed forces and an equal number must be recruited to meet Army and Navy needs between now and next July. There is in addition, it was stated, a serious shortage of nurses in many hospitals and elsewhere where their services are vital in meeting the health needs of the civilian population.

The wholehearted cooperation of each member of the nursing profession and of all those who employ nurses—hospitals, industrial and business firms, physicians and the general public—will be necessary if these shortages of nurses are to be surmounted, the Directing Board said.

The cooperation of all nurses, both active and retired will be particularly required by the new Nursing Division of the Procurement and Assignment Service. This division will (1) determine the availability for military service or essentiality for civilian service of all nurses eligible for military service and submit such determinations to the American Red Cross for use in procurement of nurses for the armed forces, (2) promote plans for maximum utilization of full time nurses and those who are able to serve only part time, (3) develop and maintain a roster of all graduate registered nurses and (4) develop and encourage sound methods of supplementing the work of nurses with non-professional personnel.

To meet the serious discrepancy between supply and demand for nursing service, five overall steps are being undertaken. First, the requirements necessary to provide proper nursing care for those in the armed forces have priority over all others. They must and will be met, the Directing Board said. More than 36,000 nurses now are with the armed forces, and the American Red Cross, which is the recruiting agency for the armed forces, will recruit another 36,000 between now and June 30, 1944 in cooperation with the Nursing Division of the Procurement and Assignment Service.

Second, concerted effort will be made this fall to bring back into active nursing the thousands of registered nurses who have left the profession because of marriage or to enter other occupations.

Third, to fill still further the gap between the supply of, and civilian needs for, nursing services, more Red Cross nurse aides are being recruited to augment the 72,960 certified and the 100,000 enrolled in classes on June 1. These aides supplement the work of and help relieve the burden of those nurses who are serving their country in the less spectacular role of hospital duty.

Fourth, an educational program is being designed to bring about a better conservation and utilization of nurses.

The fifth step aims at meeting the nation's increasing need for nurses. The new Division of Nurse Education of the United States Public Health Service has set a goal of 65,000 new students in schools of nursing, to be recruited this year for the U S Cadet Nursing Corps, which was established by the recently enacted Bolton-Bailey Act. Under the provisions of this act, assistance also will be given to those retired registered nurses who will require refresher courses before reentering service.

PUBLIC HEALTH UNDER HITLER

According to *Dagens Nyheter*, July 21, TT reports from Oslo that epidemics are spreading so quickly in Norway that hospitals can no longer receive scarlatina patients, who must in future be isolated at home. Medicinal-direktor Dr T Ostrem has emphasized that hospitals are to accept only patients who are seriously ill with scarlet fever.

Nova Press, July 10, reports that all doctors and hospital attendants born between 1903 and 1911 and hitherto unmobilized are ordered to report for mobilization.

According to *De Tijd*, June 30, the Central Press Service of the NAF has announced that Dutch women working in Germany have now become eligible for maternity allowances. At the birth of a child they will get free nursing and also an allowance if the birth takes place in Holland. In addition they will also get a maternity allowance, beginning six weeks before the

probable date of confinement and ending six weeks after the birth of the child. This allowance will be based on the average weekly wage earned during the last thirteen weeks but will not be less than 13 reichsmarks daily. Expectant mothers may not be dismissed during pregnancy, unless they agree, in which case they will lose these benefits. Six weeks before confinement they must request to be relieved of all work, and they will not accept any work during the six weeks following confinement.

An underground hospital for several hundred patients has, on the initiative of the Red Cross, been built close to a Berlin hospital as better protection for sick persons from air attacks, according to *Transocean*, July 13. As soon as the alert is given, all patients of the hospital will be taken to these shelters, which are equipped with a modern operating room. In order to

be prepared for every emergency, night operations will henceforth be exclusively carried out in this operating shelter. Sterile material for seventy operations will constantly be kept in readiness. An x-ray department is available. This underground hospital will also serve as protection for pregnant women. Ventilation and electric lighting have been installed. The walls are covered with luminous paint, enabling the nurses to carry out the most urgent duties even if the electric lighting should break down.

As a result of many cases of infantile paralysis at Montluçon and vicinity the prefect of the Allier has forbidden all meetings in the town and district, *Radio Paris*, July 8, reports. Not only cinemas and theatrical productions have been suspended but all festivals, presentations of prizes, political reunions and baby shows. The Montluçon arrondissement has been barred to holiday makers and campers.

According to *Aibetaren*, Stockholm, July 21, a violent epidemic of diphtheria is raging in Narvik with numerous deaths. A Baptist church and a large private building which have been converted into hospitals to receive those who are infected are already crowded. Twenty persons have been found to have spread the infection without being ill themselves.

HOSPITALS FAIL TO RETURN QUESTIONNAIRES

Many hospitals have not returned the questionnaire recently sent out by the Procurement and Assignment Service. If this questionnaire is not returned immediately, hospitals will have to be appraised on the basis of old information and therefore will not receive as satisfactory allocation of house staff. Prompt returns are imperative.

ORGANIZATION SECTION

OFFICIAL NOTES

POSTWAR PLANNING FOR MEDICAL SERVICES

The Committee on Postwar Medical Service met in Chicago on June 5, 1943. There were present

representing the American Medical Association,

Brigadier General Fred W. Rankin

Rear Admiral Dallas G. Sutton

Dr. James E. Paullin

Dr. H. H. Shoulders

Dr. Alan Gregg

Dr. Warren F. Draper

Dr. Roger I. Lee

representing the American College of Surgeons,

Dr. Irvin Abell

Dr. Everts A. Graham

Dr. Arthur W. Allen

Dr. James M. Mason

Dr. Elmer L. Henderson

representing the American College of Physicians,

Dr. James E. Paullin

Dr. Ernest E. Irons

and by request Dr. Morris Fishbein and for a short time Dr. Olin West.

The discussion was largely exploratory. It was the sense of the meeting that as there are many organizations for postwar planning it might be well to assemble and maintain a current list of these different organizations and of their activities. It was pointed out that this committee, as a medical and professional committee at this time was not related to other postwar planning organizations although such relationships might come later. It was pointed out that postwar was an indefinite term and should be perhaps taken in the broader sense perhaps ten years after the actual cessation of hostilities. Dr. Paullin felt that this committee ought to be ready to appoint other subcommittees either on request or in anticipation of request on such general topics as

- 1 Nutrition
- 2 Infectious Diseases
- 3 Child Welfare
- 4 Maternal Welfare
- 5 Mental Welfare and perhaps others

TRENDS IN MEDICAL SERVICE

There was considerable discussion rather general about the trends of medical service. It was pointed out that the rural areas would be an increasing problem for medical service and that probably the Public Health Service would have wider activities in the future than in the past. The general problem of district hospitals was discussed, particularly in its relation to medical service in rural areas.

RELOCATION OF PHYSICIANS

It was agreed that relocation of physicians would very likely represent a tremendous problem. Some of the young physicians would have had inadequate internships. There would seem to be a large demand for residencies and for opportunities in which returning physicians could make a transition from the army pay to some sort of an assured income without too great an interruption and without the necessity perhaps of slowly building a practice by the old method.

POSTGRADUATE EDUCATION

The necessity of postgraduate education was stressed. It was pointed out that there was a committee already vigorously at work on graduate training in the armed forces and likely the same committee or a continuing committee might function

after the war. It was pointed out that postwar graduate training would probably not be restricted to the Americas on account of the situation in nearly all of Europe. A suggestion was made that the American embassies might have an educational attache just the same as they have a naval and military attache.

In the problem of the continuing program of medical education, it was felt that research must play a large part. It was also pointed out that presumably many of these doctors would need reeducation in the doctor-patient relationships. Very likely the Public Health Service would play a large part in the accelerated redistribution of physicians, unless the process was very slow.

It was agreed that this committee of the American Medical Association appointed by the Trustees ought to have the authorization of the House of Delegates of the American Medical Association. [This authorization was given by the House of Delegates at the meeting of the House of Delegates which took place a few days later.—Ed.]

CURRENT SITUATION

During the interval since the first meeting events have moved rapidly. At the moment the emphasis seems to rest on finding a peace that will be permanent. However as the country approaches the end of the second year of actual conflict more and more civilian doctors have joined the armed forces. The duration of internship will likely be shortened to nine months. Medical schools have soldier and sailor students and the coming winter will bring many troubles to civilian communities shorn of their doctors, and to understaffed medical schools and hospitals. Medical research except as related to the war effort has disappeared. Many doctors have now been in the armed forces over a year a goodly number for two years and some for three years.

The following problems seem pressing for consideration

1 Relocation or redistribution of physicians returning from the armed forces. This will entail the setting up of some form of information center and clearing house.

2 Cooperation in planning or advising in such governmental plans for postwar vocational training periods which affect physicians and medical students and which are now being actively discussed.

3 Graduate and postgraduate medical education for the returning physicians.

4 Organization of plans by which the younger men especially may complete internship and residencies and by which residencies and specialist training may be made available.

5 Plans for the educational rehabilitation in medicine through all gradations of a varying number of individuals of those countries whose medical systems have been largely eliminated in the last few years. Obviously this will depend on many conditions now unknown. But the rehabilitation of systems of medical service and medical education for medical practice may well be both tremendous and lengthy.

6 There are of course other problems some of which may seem to the committee to be more urgent than the ones listed. In any event it seems essential to begin consideration of these problems.

7 A proposal has been made that the committee consider the inclusion in a subcommittee of representatives of the younger group of medical officers of the Army and Navy.

8 The committee should consider also the sending of a questionnaire to a sampling of medical officers of the Army and Navy as to their desires and needs as related to the problem of education, internships, residencies, relocation, salaried positions and similar aspects of postwar rehabilitation.

[Another meeting is scheduled for the near future.—Ed.]

Medical News

(PHYSICIANS WILL CONFIR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF INTEREST OR OF GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Physicians Needed—The Los Angeles County Civil Service Commission announces examinations for the positions of physician M D head anesthetist and chief physician, M D (tuberculosis) in the Los Angeles County Department of Charities which includes the Los Angeles County Hospital Rancho Los Amigos Honda and Olive Sanatorium, Olive View. Physicians interested in any of these positions should write to the office of the commission, Room 102, Hall of Records, Los Angeles 12, for full information. Applications must be filed on or before October 22 for the physician and anesthetist positions and by September 30 for the chief physician position.

Lectures on the Heart—Under the auspices of the California Heart Association Dr Jinsley R Harrison professor of medicine Bowman Gray School of Medicine of Wake Forest College Winston-Salem N C, will deliver a series of lectures in San Francisco November 4-6, Los Angeles November 11-12 and San Diego November 9. His subjects will include "The Abuse of Rest in the Treatment of Cardiovascular Disease," "Gastrointestinal Disorders Simulating Angina Pectoris," "Some Conditions Commonly Confused with Coronary Thrombosis" and "Some Common Errors in the Interpretation of Electrocardiograms as Indicating Coronary Artery Disease." The program will also include a clinical pathologic conference.

DISTRICT OF COLUMBIA

Annual Scientific Assembly—"Medical Progress Since Pearl Harbor" is the theme of the fifteenth annual scientific assembly of the Medical Society of the District of Columbia, to be held at the Mayflower Hotel Washington, September 30-October 2. Among the speakers will be

Colonel Raymond E Scott M R C, U S Army, Treatment of Injuries in Combat Zone
Capt Camille M Sharr (MC) U S Navy, Treatment After Evacuation from Combat Zones
Capt Winchell M Crug (MC) U S Naval Reserve Injuries of the Head
Major Brian B Blades, M R C, U S Army Injuries of the Chest
Comdr Louis E Gilje (MC) U S Navy Injuries of the Abdomen
Col Lloyd G Lewis M C A U S Injuries of the Genitourinary Tract
Dr Robert V Funsten, Charlottesville Va, Injuries of Bones and Joints
Dr Claude C Coleman Richmond, Va Neurovascular Lesions of Extremities
Dr Robert H Ivy, Philadelphia Plastic Surgery
Major Gen Norman T Kirk, surgeon general of the U S Army, Sulfonamides in Prevention and Treatment of Wound Infection
Colonel Roy D Halloran M C A U S Neuropsychiatric Problems in the Army
Major Murray Sanders, M C A U S, Epidemic Keratoconjunctivitis
Dr Edward A Cafritz, Washington, D C War on Appendicitis
Dr Henry W Cave New York Sulfonamides in the Preparation and Care of Patients for Intestinal Operations
Lieut Col Thomas B Turner, M C, A U S, Present Day Management of Venereal Diseases in the Armed Services
Dr Andrew C Ivy, Bethesda, Md, Cirrhosis of the Liver
Dr Thomas Parran surgeon general of the U S Public Health Service, Pandemic Influenza
Dr Jesse G M Bullowa, New York, The Pneumonias
Lieut Col Baldwin H E W Lucke M R C U S Army, The Renal Lesions of the Crush Syndrome and Other Forms of Hemoglobinuric Nephrosis
Capt Emanuel B Schoenbach, M C, A U S, Meningitis—Its Diagnosis and Treatment
Capt Juanita Redmond, N C, U S Army Nursing Experiences on Bataan
Dr Rolla E Dyer, Bethesda, Endemic and Epidemic Disease, Including Tropical Diseases
Philip Drinker, Ch E, Boston, Medical Service in Industry
Dr Warfield T Longcope, Baltimore, Civilian Medical Practice
Dr Harvey B Stone, Baltimore, Civilian Surgical Practice
Dr Malcolm T MacEachern, Chicago, Hospital and Administrative Problems
Dr Arthur C Christie, Washington, Misleading Concepts Arising from Mobilization
Dr Oscar B Hunter, Washington Blood Transfusions with Special Reference to Reactions and the Rh Factor
Dr John B Alsever, surgeon, U S Public Health Service Reserve, The Current Status of Blood Substitutes
Lieut Col Aubrey O Hampton, M C, A U S, Recent Advances in X Rays
Comdr Omar J Brown (MC), U S Navy, Malaria—Its Control and Treatment
Read Admiral Ross T McIntire, surgeon general of the Navy, Problems of Postwar Medicine
Brig Gen Albert W Kenner, M C, U S Army, Medical Experiences in Army Warfare

Guest speakers at special luncheon sessions will include Major Margaret D Craighill, M C, A U S, on "Women in the Army Medical Department," September 30, Dr Jui Heng Liu, former minister of public health for the government of China, "Medical Progress in China," October 1, and Mr Edward T Folliard, journalist and radio commentator of Washington, D C, "What is Happening to Our World," October 2.

ILLINOIS

Rocky Mountain Spotted Fever—The state laboratory has confirmed diagnosis of a case of Rocky Mountain spotted fever near Chester. The patient was a 12 year old boy.

Dr Sievers Named Assistant State Health Director—Dr Jerome J Sievers, assistant to the chief of the division of communicable diseases, Illinois Department of Public Health, Springfield, has been appointed assistant state health director. The appointment became effective on September 1. Dr Sievers, who graduated at the University of Illinois College of Medicine in 1935, received his M S Ph degree at the University of Michigan in 1939. He has been connected with the Illinois department of health since 1939.

Grant to Study Penicillin—The University of Illinois has accepted a grant of \$25,000 a year for three years from the Upjohn Company of Kalamazoo, Mich, for the academic study of the structural composition and possible synthesis of penicillin. The grant provides for an enlarged three year research chemistry project under the direction of Herbert E Carter, Ph D, in the department of biochemistry at Urbana amplifying both an earlier cooperative research project at the school and the bacteriologic and other research now being conducted at the Upjohn Company's laboratories at Kalamazoo.

Chicago

Personal—Lola Armstrong Ponton, executive secretary of the Illinois Association for the Crippled since it was organized, has resigned. At the recent annual meeting of the Illinois Psychiatric Society Dr Clarence A Neymann was chosen president. Other officers include Drs Hugh T Carmichael vice president, and Frances Hannett, secretary-treasurer, all of Chicago.

Rongetti Seeks to Have License Restored—Amante Rongetti, under charges in the Cook County Court of practicing medicine without a license, filed a petition in superior court on August 18 for a writ of mandamus to compel Frank G Thompson, Mount Vernon, Ill, director of the state department of registration and education, to expunge an order of May 4, 1932 which revoked his license, newspapers reported. He was said to have charged that the action was unconstitutional and that the order was issued without due process of law.

William Hamlin Wilder Memorial Foundation Created—The Institute of Medicine of Chicago announces the establishment of the William Hamlin Wilder Memorial Foundation which has been made possible through a gift from Mrs Wilder. Dr Wilder was professor emeritus of ophthalmology at Rush Medical College at the time of his death in 1935. He was a founder fellow of the Institute of Medicine and a former member of its board of governors. The first lecture under this foundation will be delivered by his son, Dr Russell M Wilder chief, Civilian Food Requirements Branch, War Food Administration, Washington, D C, who will speak on "Nutrition and the Human Eye" on the last evening of the two day postgraduate assembly on Nutrition in Wartime sponsored by the Institute of Medicine to be held at the Palmer House, November 17-18.

KENTUCKY

State Medical Meeting—The annual session of the Kentucky State Medical Association will be held in the Brown Hotel, Louisville, October 5-6. The program has been contributed by wartime graduate medical meetings under the auspices of the American Medical Association, the American College of Physicians and the American College of Surgeons. Among the speakers will be

Lieut Col Claude S Beck M C A U S Burns
Dr Eugene A Stead Jr, Atlanta, Ga, Shock
Dr Roy R Kracke Emory University Ga Blood Perfusion
Brig Gen Fred W Rankin M R C and Lieut Col Burr V Carr M C, A U S, Current Trends in Military Surgery
Dr Charles B Stacy, Pineville Medical Problems in Kentucky
Dr Jacob A Bargen, Rochester, Minn, Chemotherapy in Digestive Organs
Dr Alexander E Brown, Rochester, Chemotherapy (a) In Gen urinary Infections and (b) General Consideration

Dr Herman I Kretschmer Chicago President Elect of the American Medical Association Medical and Surgical Diseases of the Prostate Gland

Brief Gen David N W Grant M C U S Army We Are Not Content

Dr Ben Wilcox Smock Louisville Where To Surgery?

Dr Edward I Turner Nashville Tenn Classification of Dysenteries

Dr Arthur W Allen Boston Thrombophlebitis and Pulmonary Embolism

On Wednesday a symposium on general surgery will be presented by Dr Allen on Gastric and Duodenal Ulcers Surgical Management and Neurovascular Lesions of the Extremities and Dr Warren H Cole Chicago Gas Gangrene and Intestinal Obstruction

MASSACHUSETTS

Tufts Announces Change in Program for Anniversary Celebration—On September 22 Col Raymond W Bliss assistant to the surgeon general of the U S Army will discuss Plans and Operations of the Surgeon Generals Office in connection with the fiftieth anniversary celebration of Tufts College Medical School Boston September 15 October 6 Portraits of Drs Timothy Leary and Cadis Phipps professor emeritus of pathology and professor of medicine respectively will be presented during the exercises on September 29 These dates differ from those announced previously by Dr Harry Blotner Boston secretary of the Tufts Medical Alumni Association (THE JOURNAL, September 11 p 103) On October 6 the anniversary celebration will conclude with a meeting in the John Hancock Hall at which Dr Alonzo K Paine Boston president, Tufts Medical Alumni Association will preside The speakers will include

Karl T Compton LL.D. president Massachusetts Institute of Technology Cambridge Some Evolutionary Trends in Professional Education

Capt A Warren Stearns (MC) U S Naval Reserve dean on leave of Tufts College Medical School Boston In Retrospect

Comdr Bartholomew W Hogan (MC) U S Navy Navy Medicine on the Home Front and in Combat Areas

Leonard Carmichael LL.D. president Tufts College Some Distinctive Characteristics of Medical Education at Tufts

At this time A History of Tufts College Medical School prepared by Dr Benjamin Spector professor of anatomy and professor of the history of medicine at Tufts will be presented

MICHIGAN

James L Wilson Goes to Professorship in New York

—Dr James L Wilson associate professor of pediatrics at Wayne University College of Medicine Detroit has been appointed chief of the childrens medical service at Bellevue Hospital and professor of pediatrics at New York University College of Medicine New York Dr Wilson graduated at Harvard Medical School, Boston in 1926

Changes in Health Officers—Dr Neal N Wood Mackinac Island health director of Charlevoix Emmet Otsego and Antrim counties, has been appointed in charge of the Bay County department of health succeeding Dr Douglas A Fryer Bay City resigned—Dr Addison D Aldrich Houghton has been named director of the Houghton-Keweenaw-Baraga health department—Dr Mordechai A Elstein was recently named health officer of Delta County it is reported

Graduate Courses—The Michigan State Medical Society in cooperation with the University of Michigan Medical School Ann Arbor Wayne University College of Medicine Detroit the Michigan Department of Health and the Wayne County Medical Society announces the extramural postgraduate courses for the autumn of 1943 The centers and dates are Ann Arbor October 12 and November 9 Battle Creek October 5 and 19 Flint October 12 and 26 Grand Rapids October 12 and November 9 Lansing October 7 and 14 Mount Clemens October 13 and 27 Saginaw October 19 and November 16 and Traverse City October 8 and November 12 On the first day the program will include lectures on the Recent Advances in the Management of Cardiac Irregularities and Syphilis Serologic and Clinical Findings in Relation to Treatment and a panel discussion on Evaluation of the Surgical Risk In addition to a panel discussion on Newer Drugs and Their Use in Practice the program for the second day will include lectures on Fatigue Its Increasing Significance in Wartime and Practical Problems in the Management of the Menopause An intramural course on Electrocardiographic Diagnosis will be held at the University Hospital Ann Arbor November 1-6 Additional information may be obtained from the committee on postgraduate education Room 2040 University Hospital

MISSISSIPPI

Dr Guyton Retires as Dean—Dr Billy S Guyton has resigned as dean of the University of Mississippi School of Medicine University, effective August 31 Dr Guyton who received his master's degree at the University of Mississippi has been associated with the medical school since 1915 first as professor of bacteriology and pathology and later as professor of minor surgery He has been dean since 1935 Dr James B Looper, recently appointed assistant dean of the school (THE JOURNAL, July 31, p 959), has been named to succeed Dr Guyton, effective September 1

NEW YORK

Dr Tainter Named Professor of Physiology at Albany—Dr Maurice L Tainter, director of research of the Winthrop Chemical Company Inc, Rensselaer, has been appointed professor of applied physiology at the Albany Medical College The appointment to the medical school will not interfere with his activities at Winthrop Prior to his association with Winthrop Dr Tainter was professor of pharmacology at the Stanford University School of Medicine and professor of pharmacology and head of the division of physiologic sciences at the College of Physicians and Surgeons School of Dentistry San Francisco

District Meetings—On September 21 the Third District Branch of the Medical Society of the State of New York held its annual meeting in Troy Among the speakers were Col Eugene R Whitmore M C U S Army Washington D C on Postwar Problems in Tropical Diseases in Civilian Practice The fifth district branch devoted its September 22 meeting to a symposium presented by the department of obstetrics of the Syracuse University College of Medicine In addition Dr Leon H Griggs Syracuse among others discussed 'Common Diseases of the Skin' The sixth district branch will be addressed on September 28 among others by Lieut Herbert Brown Jr (MC), U S Naval Reserve, on Physiologic Considerations in the Treatment of Burns Dr Richard B Cattell Boston among others will address the seventh district branch in Rochester September 30 on Recent Improvements in Biliary Tract Surgery

New York City

Personal—Dr George G Ornstein has been appointed professor of medicine and attending physician (chest diseases) at the New York Polyclinic Medical School and Hospital—Barry G King Ph.D., recently resigned as assistant professor of physiology at Columbia University College of Physicians and Surgeons to accept a commission as lieutenant in the U S Naval Reserve as a physiologist assigned to medical research at the Naval Research Institute National Naval Medical Center Bethesda Md—Dr James C Magee, major general U S Army formerly surgeon general who just returned from a trip to the troops in England and North Africa lectured before the faculty and students of the New York University College of Medicine recently on military medicine with special reference to tropical diseases—Gordon T Broad assistant to Dr Edward M Bernecker commissioner of hospitals has been appointed a deputy commissioner Mr Broad has been in city service since 1912 and since February of this year has acted as food administrator for city institutions

Postgraduate Course in Industrial Medicine—To meet the continued wartime need for a general training course for physicians engaged in or desiring to enter into industrial practice, the Long Island College of Medicine Brooklyn has announced its second postgraduate course in industrial medicine to be given in Brooklyn November 1-12 The course designed for physicians has been limited to fifty A limited number of others will be permitted to attend as auditors Dr Thomas D Dublin associate professor of preventive medicine and community health which is sponsoring the course will be in charge The program will consist of afternoon and evening lectures at the college and morning clinics in the medical departments or nearby industrial plants Assisting Dr Dublin in the formulation and development of the course are Dr Cassius H Watson medical director of the American Telephone and Telegraph Company alumnus and trustee of the college Dr John J Wittmer medical and personnel director of Consolidated Edison Company alumnus and Alired R Crawford AB assistant to the dean in the department of administration The general topics of the lecture course are various phases of which will be discussed include 'The Physician in Industry and His Field Planning an Industrial Medical Department' Evaluating the Health Status of a

Worker, "Occupational and Nonoccupational Incapacitation," "Community Factors in the Health of the Worker," "Industrial Accidents," "Protecting the Place of Work," "Surgical Management of Industrial Injuries," "Industrial Toxicology and "Special Wartime Problems in Industrial Medicine."

OHIO

Health Supervisor Wins Howell Medal—Dr. Lyman W. Childs, Orlando, Fla., health supervisor in the Cleveland Public Schools from 1910 to 1935, has been announced as the recipient of the William A. Howell Medal for distinguished service in the field of school health. The award will be presented to Dr. Childs at the annual meeting of the American School Health Association in New York, October 11. Dr. Childs retired in 1935.

Academy of Medicine Opposes Medical Care Plan—On August 6 the board of directors of the Academy of Medicine of Cleveland at a special meeting voted their opposition to the proposed medical service plan and went on record that it will actively oppose such a plan. The medical service plan is one instigated by the Cleveland Medical Service Association, which was set up in 1942 to assume leadership in drawing up a plan for citizens of Cuyahoga County after a vote of the academy had rejected the approval of such a plan (*THE JOURNAL*, Dec. 19, 1942, p. 1328). In presenting a statement, the board of directors of the Academy of Medicine of Cleveland said that it has become increasingly apparent that the majority of the practicing physicians of Cuyahoga County are definitely opposed to the medical care plan instituted by the Cleveland Medical Service Association. Medical service plans have twice been defeated by vote of the academy membership, it was stated. This position is supported by the majority of non-members of the academy residing in the county.

PENNSYLVANIA

State Medical Meeting—The ninety-third annual session of the Medical Society of the State of Pennsylvania will be held at the Bellevue-Stratford Hotel, Philadelphia, October 5-7, under the presidency of Dr. Robert L. Anderson, Pittsburgh. Among the speakers on the program will be

Robert A. Hingson Jr., assistant surgeon, U. S. Public Health Service, An Analysis of the First Ten Thousand Obstetric Cases Managed with Continuous (caudal) Analgesia with Report of Author's First Twelve Hundred Cases
 Drs. Michael G. Wohl and Harold F. Robertson, Philadelphia, Bromide Intoxication—Some Observations on Its Treatment with Sodium Chloride and Desoxycorticosterone
 Dr. John B. Montgomery, Philadelphia, The Role of Gynecologic Lesions in Uteral Obstructions
 Dr. Vincent T. Curtin, Scranton, The Use of Blood Plasma Intraperitoneally in the Treatment of Gastroenteritis in Infants
 Drs. Paul M. Rike, Duquesne, and Frank J. Gregg, Pittsburgh, Cardiovascular Survey of Supervisors
 Dr. Louis H. Clerf, Philadelphia, Prevention of Bronchiectasis
 Dr. James M. Alesbury, Philadelphia, Obstetric Deaths Resulting from Operative Deliveries Other than Cesarean Section
 Dr. George F. Cahill, New York, Hormonal Tumors of the Adrenal Gland
 Dr. Francis C. Grant, Philadelphia, Surgical Treatment of Cranial Trauma
 Dr. Joseph A. Hepp, Pittsburgh, Menopausal Management—A Further Report on Diethylstilbestrol
 Dr. Thomas M. Durant, Philadelphia, Thiocyanate Therapy in Hypertension
 Dr. Burton Chance Jr., Philadelphia, Evaluation of the Kenny Method in Chronic Infantile Paralysis
 Dr. Robert L. Moorhead, Brooklyn, Complications of Mastoiditis
 Dr. Eugene P. Pendergrass, Philadelphia, The Roentgen Diagnosis of Some of the Lesions Around the Diaphragm
 Dr. Charles M. Hower, Bloomsburg, The Problems of the Rural Surgeon
 Dr. Leo H. Cripe, Pittsburgh, Allergic Dermatitis—Diagnosis and Treatment
 Dr. Norman M. MacNeill, Philadelphia, Infant Feeding in a Rationed Era
 Dr. Walter Hughson, Abington, Hearing Aids
 Dr. Wendell J. Stainsby, Danville, The Treatment of Pneumonia in General Practice
 Dr. Thomas A. Shallow, Philadelphia, The Surgical Aspect of Acute Pancreatitis
 Dr. Charles F. Kutscher, Pittsburgh, Retinal Arteriolar Changes in Sclerosis and Hypertension
 Drs. Robert Denison Harrisburg and Joseph C. Yaskin, Philadelphia, Medical and Surgical Masquerades of the Depressed States
 Drs. Henry D. Rentschler and John W. Settle Jr., Sayre, Treatment of Impaired Hearing by Radiation of Excessive Lymphoid Tissue in the Nasopharynx
 Dr. David M. Davis, Philadelphia, The Absence of Pain in Serious Urologic Disease
 Dr. Wallace M. Yater, Washington, D. C., Selection and Interpretation of Laboratory Procedures
 Dr. W. Wallace Dyer, Philadelphia, Masked Hypoglycemia
 Drs. Francis D. W. Lukens and Francis C. Dohan, Philadelphia, Remission of Diabetes Mellitus
 Surg. Gen. Norman T. Kirk, U. S. Army, The Adaptation of War Surgery to Civil Surgery
 Dr. Guy A. Hunt, Butler, Glaucoma—Early Signs and Symptoms
 Dr. John C. Ullery, Philadelphia, Continuous Spinal Anesthesia in Gynecology and Obstetrics

Dr. Henry K. Sangree, Philadelphia, Prostatic Carcinoma: Endocrine, Roentgenologic and Surgical Therapy
 Dr. Adolph G. DeSanctis, New York, Sulfonamides in Pediatric Practice
 Capt. Jack Edward Berk, M. C., A. U. S., Trends and Shortcomings in the Approach to Gastrointestinal Diseases, a Review Based on Experience in an Army General Hospital
 Dr. Mix M. Strumit, Bryn Mawr, Post Transfusion Hemolytic Reactions
 Louis Schwartz, medical director, U. S. Public Health Service, Washington, D. C., New Developments in Industrial Dermatitis
 Dr. James A. Cown Jr., Pittsburgh, The Principles of Preparation for and the Management of Elective Surgery in Children
 Dr. Ross Golden and Arthur P. Stout, New York, Correlation of the Roentgenologic and Pathologic Aspects of Carcinoma of the Stomach

A special general assembly will be held Wednesday evening on the art and science of therapeutics at which the speakers will be Drs. Abraham H. Aaron, Buffalo, Calvin M. Smyth Jr. and Hobart A. Reimann, Philadelphia, and Harold B. Gardner, Pittsburgh.

Philadelphia

Tribute to the Late Martha Tracy—The Alumnae Association of the Woman's Medical College of Pennsylvania announces the publication of a series of addresses delivered at a service in memory of the late Dr. Martha Tracy, dean of the college from 1918 to 1940. Copies of the booklet may be obtained from the alumnae office at the Woman's Medical College. The price is \$1 per copy. Proceeds will be placed in the Tracy Memorial Fund.

The Alvarenga Prize Lecture—Ernest C. Faust, Ph.D., professor of parasitology and acting head of the department of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans, will deliver the annual Alvarenga Prize Lecture of the College of Physicians of Philadelphia on October 13. His subject will be "Some Modern Conception of Amebiasis." In July Dr. Faust was announced as the winner of the Alvarenga Prize for "outstanding contribution to our knowledge of parasitology and tropical medicine" (*THE JOURNAL*, August 7, p. 1024).

VIRGINIA

Special Society Election—Dr. Joseph E. Barrett, Marion, was chosen president of the Mental Hygiene Society of Virginia at its meeting in Roanoke recently. Mabel F. Martin, Ph.D., is the secretary and Frank W. Gwaltney, Richmond, executive secretary. A feature of the recent meeting was a public meeting devoted to a discussion of alcohol, a state and psychiatric problem, by Hunter Miller, formerly state senator, and Dr. Robert V. Seliger, Baltimore.

Personal—Dr. Emmett Tribble Gatewood, Richmond, was elected president of the Virginia Society of Ophthalmology and Otolaryngology recently. Dr. Samuel D. Sturkie, former health director for the Marion-Bristol area, has been named director of public welfare in Lynchburg. He succeeds the late Mosby G. Perrow, Ph.D.—A portrait of Dr. Roslier W. Miller, past president of the state medical society, was recently unveiled at a regular meeting of the Richmond School Board. Dr. Miller has been a member of the school board for nearly twenty-three years and has served as chairman since 1928. Elias W. Langs, assistant surgeon, U. S. Public Health Service, has been appointed health officer of Norfolk County.

State Medical Meeting—The Medical Society of Virginia will hold its annual meeting at the Hotel Roanoke, Roanoke, October 25-27 under the presidency of Dr. John M. Emmett, Clifton Forge. Among the speakers will be

Dr. William M. Bickers, Richmond, Functional Uterine Bleeding
 Dr. Charles Stanley White, Washington, D. C., Demerol: A Synthetic Morphine Substitute
 Dr. Matt O. Burke, Richmond, Medical Progress During the Last Sixty Years
 Dr. Charles J. Frankel, Charlottesville, The Kenny Treatment for Poliomyelitis: One Year of Observation
 Dr. David C. Wilson, Charlottesville, The Treatment of Alcoholics
 Addicts
 Brig. Gen. Charles C. Hillman, M. C., U. S. Army, Medical Operations in the Pacific Theaters
 Dr. Ernest L. Copley, Richmond, Agranulocytic Angina—A Drug Hazard
 Dr. Frank S. Johns, Richmond, The Treatment of New Growths at the Rectosigmoid
 Dr. Charles L. Harrell, Norfolk, Tuberculosis in the Aged
 Lieut. Col. Ernest T. Trice, M. C., A. U. S., The Continuance of Symptoms After Surgery of the Bile Tract
 Dr. Eugene L. Lowenberg, Norfolk, Femoral Vein Ligation in the Treatment of Pulmonary Embolism Due to Femoral Thrombophlebitis
 Capt. Don S. Knowlton (M.C.), U. S. Naval Reserve, subject not announced
 Capt. John O. Owsley (M.C.), U. S. Navy, subject not announced
 Dr. Randolph H. Hoge, Richmond, Pelvic Pain
 Dr. Martin L. Dreyfuss, Clifton Forge, The Diagnostic Value of the Technic of the Aspiration Biopsy of Sternal Marrow
 Dr. Harry H. Henderson, Richmond, The Prevalence and Path of Rickettsial Diseases
 Dr. William R. Jordan, Richmond, Diabetic Coma

Dr. Dean B. C. and I. June Bur. Richmond. A. H. Matic. Atelec
to Stimulating Tissue in
D. H. H. I. K. and I. S. Larson. Th. D. Richmond. Recent
Advances in the Pharmacology of Nicotine
D. William B. McIlwaine and I. J. White. Petersburg. Reports
and Observations on About Two Hundred Cases of Whooping Cough
Dr. H. K. Beckwith. Clinton. The Diagnosis and Medical
Treatment of Pulmonary Embolism
Dr. Everett I. Evans. Richmond. Plastic Surgery of Severe Burn

Special society luncheon will be held the same day of the
American College of Physicians Virginia Section Virginia
Obstetrical and Gynecological Society Virginia Orthopedic
Society Virginia Pediatric Society Virginia Radiological
Society and Virginia Urological Society

WEST VIRGINIA

Personal—Dr. Jerome I. Andes, former instructor in the
West Virginia University School of Medicine Morgantown
and recently medical director for the Hercules Powder Com-
pany at Lawrence Kan. has been appointed director of the
student health center at the university to succeed Dr. Roy R.
Summer who resigned to enter private practice at Charleston
(THE JOURNAL July 24 p. 885).—Dr. Harry A. Garrison,
medical superintendent of the Spencer State Hospital, Spencer,
has been appointed superintendent of the Weston State Hos-
pital, Weston. He succeeds Dr. John E. Offner, Weston, who
was recently named state health officer.—Robert F. Rooth,
president of the board of control of the state department of
public assistance has been named director of the department
for the term ending July 1, 1945. He succeeds Homer W.
Hanna.

Positions in State Health Department Available—Posi-
tions now available in the West Virginia Health Department
for which applications are being accepted together with salary
range are

Public health nurse (class A)	\$1 680-1 980
Public health nurse (class B)	1 500-1 860
Public health nurse trainee	1 380-1 500
Graduate nurse	1 380-1 620
Junior engineer	2 160-2 640
Chemist	1 620-2 100
Sanitarian	1 500-2 100
Sanitarian trainee	1 200-1 500
Junior bacteriologist	1 920-2 400
Junior virologist	1 920-2 400
Technical laboratory assistant	1 500-2 100

Age limits and residence in West Virginia have been waived
for consideration of applicants for these positions. Appoint-
ments may be made at a salary above the minimum. Addi-
tional information may be obtained from the West Virginia
Merit System Council 212 Atlas Building Charleston 1

GENERAL

National Safety Congress—Stop Accidents—Speed Lim-
its will be the theme of the thirty-second National Safety
Congress and Exposition to be held at the Sherman Hotel
Chicago October 5-7. Sessions will also be held at the Mor-
rison and LaSalle hotels.

**Council of International Relations Created by Hospi-
tal Group**—A Council of International Relations designed to
promote better hospital care for the people of the world was
established by the board of trustees of the American Hospital
Association at a meeting in Buffalo on September 12. The
council will cooperate with Nelson Rockefeller coordinator of
the Office of Inter-American Affairs and plans to assist in
maintaining reciprocal relations with all hospital groups in the
world. It will concern itself with matters affecting the coop-
eration of hospitals in all countries and endeavor to promote
better hospital care for the peoples of the world through the
coordination of national hospital associations and the exchange
of information on matters of hospital administration. The asso-
ciation also has created a postwar planning commission on
hospital care to study present and prospective needs for hos-
pital care and the present practices, policies and progress of
voluntary private and public institutions caring for the sick.

Science Writers Plan Medical Publication—A special
publication committee has been appointed by the National
Association of Science Writers to explore the possibilities of
founding an official journal for the association to bring the
advances of science and medicine to a wide layman audience.
Serving on the committee will be Robert D. Potter, New
York, science editor of the *American Weekly*; William Lau-
rence of New York *Times*; Howard Blakeslee of the Asso-
ciated Press; Waldemar Kaempffert of the New York *Times*;
David Dietz, Scripps-Howard newspaper; and Lawrence Sal-
ter of the American Medical Association. Recent committee
appointments include Mr. Blakeslee as chairman of the pre-

dent's advisory committee. Mr. Laurence, chairman of the war
advisory committee and Gobind B. Lal, International News
Service chairman of the program committee. Officers of the
association are Mr. Potter, president and Capt. Stephen J.
McDonough, M. A. C. of the Office of the Surgeon General
of the Army, secretary-treasurer.

LATIN AMERICA

Health Activities in Latin America—The establish-
ment of a cooperative program to promote health and sani-
tation in the Dominican Republic was provided under an
agreement August 26, by Dr. George C. Dunham as represen-
tative of the Institute of Inter-American Affairs and Dr. Dario
Contreras, secretary of the Department of State for Health
and Public Welfare in the Dominican Republic. The agree-
ment provides for the creation in the department of state for
health and public welfare of the republic of a special technical
service to be known as the Servicio Cooperativo Inter-
Americano de Salud Publica to serve as the agency respon-
sible for the cooperative program and to constitute a separate
entity in the department of state for health and public welfare
and as an integral part of the government. The Institute of
Inter-American Affairs will furnish a group of persons to be
known as the field party to collaborate with the secretary of
state for health and public welfare. Members of the field party
will be in charge of Dr. Thomas B. Phinizy, now chief of the
party in Costa Rica. The nature and extent of the health and
sanitation projects will be determined by Dr. Contreras and
Dr. Phinizy.

Construction—Plans have almost been completed for the
Quinta Normal Health Center in Santiago, Chile, to provide
services for venereal disease, child welfare, maternity and tuber-
culosis. Provisions are also being made for an auditorium that
will seat 150 persons for desks for 20 visiting nurses and 1
sanitary engineer with 4 assistants for a milk distributing sta-
tion and for public baths and laundries. A health center is also
being planned for Valparaiso, locations for other centers have
yet to be selected. In Peru new hospitals are under way
at Iquitos, Pucallpa, Yurimaguas, San Martin Chimbote and
Tingo Maria. A health center is being planned at Lima and
a dispensary at Barranca was begun in July. In Paraguay the
new building in projects include a health center and ministry
of health building, Asuncion and an addition to the Barrio
Obrero Hospital, general improvements to the National Hos-
pital de Clinicas and a leprosy preventorium.

New Health Units—A cooperative organization has been
started in Mexico to be known as the Direccion de Cooperacion
Inter-Americana de Salubridad Publica or D. C. I. S. P. It
will function as an integral part of the department of public
health of Mexico and have offices in the department's building.
Health Centers are also being planned at Encarnacion, Villa-
rica and Concepcion.

University Project—The Department of Health of Mexico
has signed an agreement with the Tulane University of Loui-
siana School of Medicine, New Orleans, to establish and main-
tain a health unit and field training station at Boca del Rio,
Vera Cruz, with a full time resident director and staff. The
unit will function as a health center for the welfare of the com-
munity and serve as a training center for physicians named by
the Mexican department of health or by Tulane University
with the approval of the Mexican department. Patients in the
health unit of the city of Vera Cruz and in the hospitals there
and those obtained through the facilities of the Institute of
Tropical Diseases and other hospitals in Mexico, D. F. and
clinic patients of Boca de Rio will be available for study.
Funds to construct and equip the health unit building at Boca
del Rio will be provided by the Mexican department of public
health and Tulane University, but the department will provide
funds to operate the health unit as such. Additional expenses
incurred in connection with the training program for physicians
chosen at Tulane's suggestion will be paid by the university.

New Medical Organization—A new medical society orga-
nized in Asuncion, Paraguay, to be known as the El Circulo
Paraguayo de Medico, held its first general meeting on July
20. Dr. Juan Max Boettner was named president and Dr.
Manuel Riveros, vice president.

CORRECTION

Robert Collier Page—In the list of Assn. Medical
Examiners in the Medicine and the War section of THE JOURNAL
of September 4, page 40, under New York, the fifth name
listed should have been Robert Collier Page instead of
Robert Clinton Page.

The British Medical Association and the Beveridge Scheme

The stand made by the representatives of the British Medical Association against the government proposals has been described in a previous letter (*THE JOURNAL*, July 10, p 759). The discussions with the minister of health are concluded and the next stage is the issue by him of what is called "a white paper" surveying the position. The representatives of the association urged on him that this paper should be confined to a statement of the problems and not commit the government to any solution, thus facilitating frank discussion by the public and the profession. On the minister's ruling the discussions were confined to a consideration of a comprehensive health service available to the whole community. They ranged over a wide field, such as central and local administration, health centers, free choice of doctor, private practice and remuneration. The council of the British Medical Association has reaffirmed certain basic principles laid down in the association's "General Medical Service for the Nation" approved in 1938. 1 The system should be directed to the achievement of health and prevention of disease no less than to the relief of sickness. 2 There should be provided for every one a family doctor of his own choice. Consultants and specialists, laboratory and other auxiliary services, institutional provision when required, should be available through the agency of the family doctor. These recommendations and the following further ones are submitted by the council for consideration by the divisions of the association. The state should not assume control of doctors rendering personal service. It is not in the public interest to convert the medical profession into a salaried branch of government service. Free choice of doctor should be preserved and the state should not invade the doctor-patient relationship. Free choice of doctor should be reinforced by a method of remuneration related to the amount of work done. Consultants and specialists should normally be based on the hospital. For those who wish to be treated in private accommodation, whether part of a hospital or not, private consulting practice should continue as at present. The central administrative body set up for the medical service of the future should be responsible for all civilian health services. The minister to whom this body is responsible should be advised on medical matters, including personnel, by a medical advisory committee representative of the medical profession. Locally, new administrative bodies, responsible to the central authority, should cover wide areas and should be representative of the community served and, in appropriate numbers, of the local profession and voluntary hospitals.

British Surgeons Observe Russian Medical Services

A mission of British surgeons, sent to Russia by the British Council and the Medical Research Council (*THE JOURNAL*, July 10, p 752), has returned favorably impressed by the Russian medical institutes and the medical services of the army. The mission included Surgeon Rear Admiral Gordon-Taylor, consulting surgeon to the Royal Navy, Mr E Rock Carling, consultant adviser to the Ministry of Health, Major General D C Monro, consulting surgeon to the British army, and Mr R W Watson-Jones, civilian consultant in orthopedic surgery to the Royal Air Force. Two American surgeons, Col Elliott C Cutler and Lieut Col Loyal Davis, and a Canadian surgeon, Prof Wilder Penfield, accompanied the mis-

sion. The general conclusions reached by the mission were given at a reception held at the offices of the British Council. "We are convinced that the Russian soldier is in thoroughly good hands," said Mr Carling. "Many of those hands are women's hands. We came away with tremendous admiration for the Russian women and particularly for the Russian nurses. At the front we found that they could turn their hands to any thing. In a forest we came to a hospital which the nurses were enlarging in their spare time, cutting down timber, digging the ground, building the wards. After dinner they gave an extremely good cabaret show."

The organization of the Russian medical services was first rate and thoroughly well adapted to the enormous number of wounded. Their surgical work also was good. They appeared to follow the same principles as British surgeons. The system of blood transfusion was most impressive. It was carried out on a colossal scale in the best way. The arrangements for the collection of blood were beyond criticism. The enormous numbers dealt with was shown by the fact that one Moscow institution handled 500 to 800 cases a day. Ninety per cent of the donors were women, who were bled up to seven times a year. They were paid but voluntarily returned 80 per cent of what they received for war purposes. Where blood was needed it was never lacking. It was transported to the front in big airplanes and then in smaller ones to outlying parts. Airplanes were used behind the German lines for carrying wounded partisans to concealed small hospitals. The Russians appeared to have solved the problem of getting special cases into the hands of specialists as soon as possible. Even in advanced hospitals 8 to 10 kilometers from the front different types of cases were segregated in the hands of junior specialists, to be passed back to the special hospitals. Of the doctors now being trained in Russia 90 per cent are women, compared to the normal 50 per cent. Seventy per cent of the wounded recover so completely as to return to the battlefield. Each bottle of blood for the wounded is labeled with the donor's name, which has led to romances between the donor and the recipient.

The Prevention of Venereal Diseases

As reported in previous letters, the increase in venereal diseases due to the war has brought about a public discussion of the subject unparalleled in this country before. In his presidential address to the York diocesan conference the archbishop of York stated that there has been an increase of 120 per cent in syphilis, though the proportion of all forms of venereal disease was smaller for this war than for the last. The rise in syphilis had been mainly among women. The church must help in prevention by giving clear and definite teaching. Increased venereal disease was a symptom of increased moral laxity. The church had always condemned promiscuous intercourse but at the present day there were many who saw no harm in it if the consent of both parties was given. Some advocated compulsory notification of the disease. He thought universal compulsory notification impossible. This would tend to drive the disease underground, as the patient would delay consulting the doctor who would have to notify the authorities. But if the disease could not be checked it might be desirable to notify it in certain localities. He approved of the compulsory treatment of those proved to be centers of contagion, as adopted by the Ministry of Health. He also thought it right that instruction should be given as to how to avoid venereal disease provided this was accompanied by the statement that there was no safety except in avoiding promiscuity. Care should be taken to provide recreation in all isolated camps. More women police were required to deal with girls who hung about camps pestering the men. More intelligent teaching of the Christian view of sex was needed.

Huge Profits from the Sale of a Proprietary Pill

At the annual general meeting of Bechams Pills Ltd the chairman reported that for the eleventh successive year there were increased profits. For the past year they amounted to \$6,000,000 which was \$470,000 up on the previous year, in spite of difficulties created by the war. The raw material position was more difficult and quotas and other restrictions militated against sale expansion. The huge profits indicate the extent to which the public treats itself for constipation and even in its absence for symptoms which it imagines will yield to an aperient.

BRAZIL

(From Our Regular Correspondent)

July 30 1943

Puerperal Sepsis

Dr João M. Pereira, assistant physician of the Arthur Bernardes Maternity of Rio de Janeiro has published a study of the incidence of puerperal sepsis in 1,000 consecutive deliveries performed in that hospital at the same time presenting recent data from other hospitals of Brazil and South America. Dr Pereira emphasizes that puerperal sepsis is rather prevalent in Rio de Janeiro where many pregnant women are delivered by low standard midwives particularly in the suburbs. The mean annual maternal mortality rate for the decade 1932-1941 is 6.9 per thousand live births and out of the total of maternal deaths puerperal septicemia represents the high average of 46.8 per cent. In 1942 puerperal septicemia and infection was registered as the cause of 126 deaths or 41.5 per cent of the maternal deaths (1 death in 321 live births as against 1 in 282 in 1941). Even in the hospitals puerperal sepsis is now not uncommon. In 1911 Dr Fernando Magalhães, professor of obstetrics at the University of Rio de Janeiro began a campaign against intrauterine manipulation and excessive vaginal douching and at the same time recommended the routine use of Mouchotte metallic drains.

Dr Pereira emphasizes that the Arthur Bernardes Maternity is a free hospital that receives childbearing women from its antepartum clinic as well as directly from the homes. Most come through the Municipal Emergency Medical Service, staffed in part by medical students who do not refrain sufficiently from vaginal examination before sending the patients to the maternity. In this maternity its director Dr Clóvis Correa da Costa, is following the policy of enforcing strict measures to prevent infection primarily as a medical educational campaign. Here all patients presenting a temperature above 38°C (100.4°F) after the first twenty-four hours persisting for more than one day and showing positive signs of infection (fever, uterine subinvolution changes in the lochia) with absence of another intercurrent infection are considered infected. Also considered cases of infection are the atypical ones in which the careful examination of all organs does not disclose the origin of the fever.

As a general prophylactic measure in the antepartum clinic all the genital tract or infection are carefully treated. After entering the hospital the patients are subjected to the most rigorous aseptic care. During labor prophylactic vaginal instillations are routinely used (2 per cent mercurochrome solution every four hours) a procedure that is not yet generalized in the Brazilian maternities.

According to the data from a paper published a few months ago by Dr H. Duek, also an assistant of this maternity, the rate of infected cases was immediately halved (from 6.6 per cent to 3.3 per cent) after these routine prophylactic instillations had been adopted. Also as a prophylactic measure in the cases in which examination of the placenta discloses the retention of cotyledons or fragments of the membranes a manual uterine control is done after the plan first suggested by Gheorgiu of Bucharest followed by an intrauterine washing with boiled water. A special paper on the good results of this technique will

be soon presented by Dr Rezende Figueiredo. Still as a prophylactic measure in the cases presenting larger possibilities of infection (manual deliveries, internal versions, protracted cesareans, difficult forceps deliveries) sulfonamides and estrogens are used associated or not.

As a comparison Dr Pereira states that in the Maternidad del Salvador in Santiago, Chile, data relating to 1940 and 1941 show 889 cases of infection in 3,352 deliveries (26.5 per cent) for the former and 908 cases of infection in 3,718 deliveries (24.4 per cent) for the latter year. Recent data from the maternity service of Prof. Peralta Ramos of Buenos Aires, Argentina, present a rate varying between 10 and 15 per cent of infections. In the Buenos Aires maternity directed by Dr Palacios Costa the latest information gives only 4.5 per cent of infections. In the maternity service of Dr Gonzales in Buenos Aires the data for the last two years are 4.60 and 4.72 per cent. At the Laranjeiras Maternity under the direction of Dr Fernando Magalhães, professor at the University of Rio de Janeiro, the rate for the last year is 8.3 per cent of cases of infection with 0.6 per cent of mortality. In the 1,000 deliveries presented in Dr Pereira's paper, from the Arthur Bernardes Maternity under Dr Clóvis Correa da Costa, there were only 42 cases of puerperal sepsis, what corresponds to the general rate of 4.2 per cent for the whole group without any death. But the important point is the sharp decrease in the rate, as a response to Dr Correa da Costa's campaign: 4.88 per cent for the year 1940, 4.72 for 1941 and 0.67 for 1942.

Marriages

RICHARD BEDON JOSEY, Columbia S. C. to Miss Norma Katherine Vanderlip at Niagara-on-the-Lake, Ont., Canada recently.

EDWIN BURWELL JONES WHITMORE JR., Peterburg, Va. to Miss Claudine Price Burkholder of Richmond, July 31.

JOSEPH CULLEN HALL, Winston-Salem, N. C. to Miss Mary Catherine Cheek of Graham at Saxapahaw, August 21.

SOLOMON MURRAY RAUCHWERGER to Miss Vanda A. Martin both of Oteen, N. C. in Asheville, N. C. July 15.

SAMUEL WESTBROOK HATCHER to Miss Dorothy Marie Bonner both of Jersey City, N. J. June 10.

NICHOLAS G. BUTLER, Hartford, Conn. to Miss Helen Regma McDermott of Bridgewater, Mass., July 20.

LAWRENCE RODNEY RODGER, Amarillo, Texas, to Miss Iva Lorna Piper of Decherd, Tenn., August 6.

JOHN ALLISON HOLMES, Lawrence, Kan. to Miss Elizabeth Jane Ames of Vernon, N. Y. recently.

ANTHONY J. FREDERICK, Columbus, Wis. to Miss Roshara Bussewitz of Horicon, August 21.

SPENCER ALLEN TRUEX, Jackson, Tenn. to Dr. Barbara Mae Binkley of Nashville, recently.

RICHARD VERNON MAXWELL to Miss Anna L. Stolzenberger both of New York, July 31.

HENRY F. BERCHTOLD to Miss Florence Wilcoxson both of Springfield, Ill., August 14.

ROBERT A. CRAIG, Gary, Ind. to Miss Mildred McGarran of Indianapolis, July 10.

CARRIE J. ANDERSON to Mr. Charles Robbins both of Grand Junction, Colo., June 30.

CARL R. GREEN to Miss Evelyn Walker both of Morristown, Tenn., August 3.

LOUIS F. KREMBEIN to Miss Anna Irene Zirkler both of Baltimore, August 18.

CHARLES E. BRANCH to Miss Edna Kennedy both of Piper City, Ill., August 29.

LEON S. EISENMAN, Chicago, to Miss Ida Weinstein in New York, recently.

MOSES BENMOSEHE to Mrs. Gladys Goodman both of New York, in August.

RICHARD W. DRIVEY to Miss Elaine Thies both of Waterloo, Iowa, June 10.

Deaths

Elias Joseph Marsh & Piterson, N J, Columbia University College of Physicians and Surgeons, New York, 1900, president of the Medical Society of New Jersey, 1942-1943, formerly second vice president and for many years treasurer in 1921 president of the Passaic County Medical Society, served as president of the New Jersey Sanitary and Health Association and the Harvard Club of New Jersey, member of the House of Delegates of the American Medical Association in 1903, member of the Academy of Medicine of Northern New Jersey and the Robert McKean Medical History Club, specialist certified by the American Board of Ophthalmology, a captain in the medical corps of the U S Army during World War I and later a lieutenant colonel in the medical reserve corps not on active duty, served as senior assistant surgeon at the Herman Knapp Memorial Eye Hospital, New York, surgeon emeritus, Paterson Eye and Ear Infirmary, consulting surgeon to the Paterson General Hospital and the Valley View Sanatorium, aged 68, died in the Neurological Institute of New York, September 11, of injuries received in a fall the previous day.

William A Smith, Philadelphia, Jefferson Medical College of Philadelphia, 1896, aged 67, died, June 15, in the Jefferson Hospital

Henry Augustin Spang, New Haven, Conn, New York Homeopathic Medical College and Hospital, New York, 1891, also a dentist, for many years a member and at one time president of the local board of education, aged 74, died, June 12, in the Hospital of St Raphael of angina pectoris

Jacob Henry Spivey, Shreveport, La, Memphis (Tenn) Hospital Medical College, 1898, served on the staff of the Henderson (Texas) Memorial Hospital, aged 69, died in the Highland Sanitarium, June 25, of coronary occlusion

Julia Ione Stannard, Petoskey, Mich, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892, aged 72, died recently

Edgar Sturge & Scranton, Pa, University and Bellevue Hospital Medical College, New York, 1899, fellow of the American College of Surgeons, orthopedic surgeon to the Scranton State, Mercy and West Side hospitals, aged 74, died, June 15, of paralysis agitans

Joseph Samuel Tanner, New York, University of the City of New York Medical Department, New York, 1888, member of the Medical Society of the State of New York, aged 82, died, May 10, of heart disease

John Holsey Thompson, West Palm Beach, Fla, College of Physicians and Surgeons, Boston, 1911, aged 66, died June 12, in the Pine Ridge Hospital

Thaddeus Sims Troy, St Petersburg, Fla, Medical College of Virginia, Richmond, 1899, served during World War I, for many years on the staff of the Veterans Administration Facility in Washington, D C, serving as a special medical expert and later as senior medical officer in other facilities, retired on account of disability, Nov 26, 1941, died, June 21, of carcinoma of the prostate with metastases, secondary anemia and cachexia, aged 64

Homer B Watkins, Novapater, Miss (licensed in Mississippi in 1904), formerly health officer of Winston County, aged 63, died, June 20, of coronary thrombosis

William M Weems, Clopton, Ala, Medical College of Alabama, Mobile, 1892, aged 74, on the staff of the Wood Hospital, Dothan, where he died, June 24, of intestinal obstruction

Iantha Jane Wetmore, Grand Rapids, Mich, Detroit Homeopathic College, 1905, aged 83, died, June 22

CAPT DONALD KARL FLESSA
1902-1943, M C, A U S

KILLED IN ACTION

Donald Karl Flessa & Babylon, N Y, Cornell University Medical College, New York, 1931, served on the staff of the Southside Hospital, Bay Shore, began active duty as a captain in the medical corps of the Army of the United States at Fort Bragg, N C, Aug 15, 1942, aged 40, was killed in action in Sicily, July 22

Bureau of Investigation

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food Drug and Cosmetic Act and in cases in which they refer to drugs and devices they are designated D D N Y and foods F N Y. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consigner, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Bo Go Ha Ma Mineral Springs Water—Striford Mineral Springs Company, Losburg, Miss. Shipped Oct. 20, 1941. Composition: a mildly alkaline water similar to Washington tap water except that it contained about twice the amount of dissolved mineral matter. Misbranded because of false and misleading statement on label. It is very soothing and healing to the kidneys and bladder. —[D D N Y F D C 587 November 1942]

Codrol—Pho-Sol Products Corporation, Kendallville, Ind. Shipped Feb. 10, 1941. Adulterated because its strength differed from and its quality fell below that which it was claimed to possess, namely, 371 per cent of cod liver oil extract (43 units of vitamin A per gram) which it did not. Misbranded for the same reason and because package did not bear an accurate statement of the quantity or contents. Also misbranded and adulterated under provisions of the law applicable to foods as reported in F N Y 57—[D D N Y F D C 571 November 1942]

Crawford's Ridia—Crawford Foods, Inc., San Jose, Calif. Shipped Jan. 10, 1941. Composition: essentially alfalfa with smaller proportions of mint. Misbranded because accompanying circular falsely represented that the product was a substitute for the secretions of the pancreas and that it would be efficacious for the relief of persons suffering from diabetes; that each tablet contained a potency equal to 2 insulin units and that by its use insulin sickness would vanish; that inulin stiffness and muscular pains that grow on the patient after a prolonged use of insulin would slowly leave the body; that the blurred vision and partial blindness induced by insulin would gradually be cleared and that this product was a natural remedy and health food adjuvant. Also misbranded under the provisions of the law applicable to foods as reported in F N Y 5819 and 2823—[D D N Y F D C 577 November 1942]

Filto Vapor Nasal Filter Outfit—Medical Products Institute, Inc., Cincinnati. Shipped Jan. 16, 1941. Composition: consisted of a pair of nasal filters, one detachable band, tweezers, filter pads, a bottle labeled

Filto-Vapor Cold Tablets and another labeled Filto-Vapor Nasal Filter Pad Fluid. The cold tablets were found to consist essentially of acetophenetidin, aspirin and caffeine and the nasal filter pad fluid essentially of camphor, menthol, eucalyptol, pine-needle oil, alcohol and a vegetable oil. Misbranded because false representation as a new and scientific continuous treatment for colds, sinus, sore throat, cough, bronchitis and la grippe since the treatment would not be efficacious for those purposes. Also misbranded because the label for the nasal filter pad fluid represented that camphor oil was an active ingredient which it was not. Further misbranded because the label of the cold tablets did not state the active ingredients and the aspirin was not listed by its common or usual name—[D D N Y F D C 582 November 1942]

Hercules Congestors—Holdfast Trust Company, Oakland, Calif. Shipped May 26, 1941. Device consisted of a metal vacuum pump and a large glass tube bearing at one end a soft rubber collar and closed at the other end with a metal cap which was threaded to screw into the pump. Misbranded because circular enclosed in each package bore the false statements: Organ Developer. This developer removes all obstructions in the organ, propels the blood rapidly through the disordered channels and a quick and favorable result follows. This simple apparatus is called upon to increase the life energy and remove the loss of strength.

In most cases results come in a short time while others of long standing require the patient use of the developer for five or six weeks. Also misbranded because label failed to bear the name and address of the manufacturer, packer or distributor—[D D N Y F D C 591 November 1942]

Lishus and Bekus Puddy—Dr. Jack on Food, Brooklyn. Shipped Jan. 13, 1941. Composition: essentially flax seed, rice, rice polishing, wheat and wheat bran. Both products misbranded because statement on carton: If troubled with Acid Stomach or fermentation etc. do not use sugar. Cook raisins or dates in with the cereal if sweet is required was false and misleading since with or without raisins or dates they did not constitute an adequate treatment for acid stomach or fermentation

Also misbranded because pictures of a robust man accompanied by the legends: Dr. Jackson at 80 and photo of Robert G. Jackson, M.D. at 60 were false and misleading since use of these products could not be depended on to produce or maintain robustness. Further misbranded because of false and misleading statements in an accompanying leaflet representing that these preparations were especially designed to relieve constipation and remove its cause by natural means; furnish sufficient roughage to stimulate muscular activity of the bowels and enough minerals to stimulate and support nervous control of those muscles besides causing three to five evacuations a day in a person ordinarily having but two movements a week. Lishus was further misbranded under the provisions of the law applicable to foods as reported in F N Y 2995—[D D N Y F D C 579 November 1942]

Lurin—Lurin Company, Cleveland. Shipped between April 8 and 19, 1941. Composition: essentially aluminum hydroxide (21 grams per hundred cubic centimeter) and water flavored with peppermint oil. Misbranded because statements on label: Alcoholic Over Indulgence and Where Used in the Treatment of Active Peptic Ulcers were false and misleading since this was not an adequate treatment for those conditions. Also misbranded because of false label claim: Combines with at least 12 times its volume of 1/10 Hydrochloric Acid since the volume of aluminum hydroxide that it contained was sufficient to combine with only 808 volumes of 1/10 hydrochloric acid. Further misbranded because statement on label: Contents 8 Fl. Oz. was false and misleading since the package contained less than 8 fluid ounces—[D D N Y F D C 589 November 1942]

McCollum's Vitamin A and D Tablets—McCollum Laboratories, Hollywood, Calif. Shipped between July 12 and 25, 1941. Adulterated because strength differed from and quality fell below that which it was represented to possess, namely: Each tablet contains 3,000 International Units of vitamin A and 100 International Units of vitamin D since each tablet contained much less than these respective amounts. Misbranded because the claim was false and misleading. Also adulterated and misbranded under provisions of law applicable to foods as reported in F N Y 2980—[D D N Y F D C 569 November 1942]

Newbro's Herpicide—Herpicide Company, New York. Shipped Oct. 14, 1940. In two forms: Regular and Odorless. Composition analysis showed both forms to consist essentially of salicylic acid, glycerin, water, alcohol and small amounts of brucine and aromatics. Misbranded because of false and misleading representations on label that it would be efficacious in treating obstinate dandruff, falling hair and general scalp and hair disorders. Further misbranded because label did not list the common or usual names of the active ingredients—[D D N Y F D C 586 November 1942]

New Food—Parke D. Brodier, trading as Parke Lee Food Company, Lorain, Ohio. Shipped Feb. 8, 1940. Composition: ground and roasted flax seed. Misbranded because of false and misleading label representations that this was an entirely new type of food, contains an all-vegetable mucin (mucilage), an excellent auxiliary food that it possessed such nutritional value as to supply important amounts of minerals, fats and proteins and thus give extra nourishment and strength besides furnishing an appreciable amount of mucin whereas it would be without value for such purposes. Further misbranded because claim: This food will be a pleasant and effective addition to the diet of any person of any age, falsely implied that the product would supply vitamin constituents which are lacking in modern foods or might have been destroyed by modern methods of preparation. Also misbranded because of statement: eminent food authorities are agreed that there exists a certain fatty acid deficiency, principally a deficiency of Linolic, Inolinic and Linolinic or Unsaturated Fatty Acids (Vitamin F) whereas authorities are not agreed that the term "vitamin F" is a proper name to be applied to the unsaturated fatty acids nor are they agreed that there are fatty acid deficiencies in the ordinary human diet. Misbranded again because false representation to be an effective treatment of symptoms of diabetes, stomach and intestinal ulcers, high blood pressure and indigestion besides enabling diabetic persons to reduce their sugar, helping them to remain sugar free and giving them extra nourishment and strength. Further misbranded because label did not conspicuously bear the common or usual name of the contents, namely, flaxseed or linseed. This product was also misbranded under the provisions of the law applicable to foods as reported in F N Y 2820—[D D N Y F D C 574 November 1942]

Orrine No. 1—Orrine Company, Washington, D.C. Shipped between April 9 and Aug. 20, 1940. Composition: essentially gold chloride, hyoscine hydrobromide, ammonium chloride and cinchona alkaloids. Misbranded because of false and misleading representations on label that treatment would be efficacious in lessening or relieving the desire or craving for liquor—[D D N Y F D C 584 November 1942]

Pinolator Inhaler and Medicament—Pinolator Company, Minneapolis. Shipped Jan. 2, 1941. Composition: the medicament bore the name: Breath O The Forest and was found to consist essentially of menthol, camphor, pine oil, thymol and a benzoate dissolved in a mixture of alcohol (60 per cent or 288 minims per fluid ounce) and water. Misbranded because label represented product to provide soothing relief and comfort in symptoms of common cold, sinus, bronchitis, asthma and hay fever and enable the user to pass through the worst hay fever season without serious discomfort. Also misbranded because claim on bottle label and carton: Ethyl alcohol 69% 130 minims per ounce was false and misleading and because carton did not declare the name or each active ingredient or the quantity and percentage of alcohol or the quantity of contents—[D D N Y F D C 583 November 1942]

DANGEROUS TO HEALTH

Because of Inadequate Warnings on Labels

[EDITORIAL NOTE—These abstracts differ from other abstracts or Notices of Judgment issued by the Food and Drug Administration of the Federal Security Agency which have appeared in these pages in that they deal with nostrums which were misbranded because their labels failed to carry adequate warnings against giving them to children or using them in those pathologic conditions in which they might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application, for the protection of the user. The abstracts that follow are given in the briefest possible form: (1) the name of the product, (2) the name of the manufacturer, shipper or consignor, (3) the date of shipment, (4) the composition, (5) the type of nostrum, (6) the reason for the charge of misbranding and (7) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Bron Cho-Line Emulsion—Johnstone Drug Sales Corporation Rochester N. Y. Shipped July 17 1941. Composition essentially creosote, calcium sodium and phosphorus compounds, benzyl alcohol, methyl salicylate and gum acacia emulsified in a mineral oil. Misbranded because label carried false claims regarding the alleged curative powers of these drugs. Further misbranded because labeling failed to bear adequate warnings against use in those pathologic conditions such as persistent cough or high fever wherein this product might be dangerous to health or to caution against unsafe duration or administration.—[D D N J, F D C 611 February 1942]

Comfort Tablets—Shipper's name not reported. Shipped March 30 1940 from St. Louis to College Laboratories, Inc. Denver who repackaged product in such a way that it was misbranded. Composition included acetophenetidin, aspirin and caffeine. Declared misbranded because of inadequate directions for use on the label and because of insufficient warning against use in those pathologic conditions wherein it might be dangerous to health and lack of caution against unsafe dosage or duration of administration for protection of users since label failed to warn that frequent or continued use might cause serious blood disturbances and that not more than the recommended dose should be taken. Further misbranded because one ingredient, aspirin, was listed on the label not by its common or usual name but by its chemical name, acetylsalicylic acid.—[D D N J, F D C 613 February 1942]

Doctor's Daughter Tablets and Dr. Wilbur's Laxative Tablets—Dr. John Wilbur Draughter Company, Westerly, R. I. Shipped April 16 1941. Composition first named product essentially calcium carbonate, sodium carbonate and sodium bicarbonate. Laxative Tablets essentially belladonna alkaloids, including atropine and laxative plant drugs. Misbranded because of lack of adequate warning on labeling against use by children or in those pathologic conditions wherein it might be dangerous to health or against unsafe methods or duration of administration or application for protection of users, since labeling did not warn that frequent or continued use might cause dependence on laxatives and that the product should not be taken when symptoms of appendicitis such as nausea, vomiting or abdominal pain are present. Also misbranded because carton did not give common or usual names of active ingredients or state the quantity or proportion of belladonna alkaloids present in the laxative tablets. Again misbranded because the envelope containing the latter did not declare the quantity or proportion of belladonna alkaloids or common or usual names of all the active ingredients since "Exl and phlodophyllum" (?) did not inform that "extract and 'podophyllum' were meant. Misbranded further in that the carton label did not accurately state quantity of contents since no reference was made to the envelope containing the 25 laxative tablets.—[D D N J, F D C 554 November 1942]

Dye's Compound Tablets and Dye's Laxative Pellets—Dr. J. H. Dye Medical Company, Buffalo. Shipped between May 8 and June 10, 1941. Composition first named product consisted of plant extracts including valeric acid and plant drugs containing alkaloids, the laxative pellets were aloin, podophyllum resin and hydrastis. The pellets were misbranded because labeling did not give adequate directions for taking them, or sufficient warnings against use in pathologic conditions wherein the product might be dangerous to health, or caution against unsafe duration of administration, for protection of user, particularly in absence of warning that frequent and continued use might result in dependence on a laxative and that a laxative should not be taken when symptoms of appendicitis are present, such as nausea, vomiting and abdominal pain. Further misbranded because of false and misleading representations that the pellets would effectively relieve headache, coated tongue, bad breath, aggravated pimply skin, lassitude, indigestion and other distressing symptoms due to temporary constipation. "Dye's Compound Tablets" misbranded because of false and misleading label representations to the effect that they would relieve symptoms of functional dysmenorrhea and other female irregularities, and accompanying conditions such as headache, nervousness, irritability, backache, nausea, rings under eyes, melanolia, hysteria, loss of appetite and pains in various parts of the body,

that they would build up physical resistance, improve digestion and help one to obtain more nourishment, that they would promote happy life and increase vitality and personal magnetism, and would be an appropriate preventive and treatment for amenorrhea, dysmenorrhea, menopause, menorrhagia, metritis and ovaritis.—[D D N J, F D C 614 February 1943]

Fernol Concentrate—Fernol Company, Chicago. Shipped between Feb 21 and Nov 15, 1941. Composition essentially epsom salt, extract of cascara sagrada and small amounts of magnesium carbonate, sodium phosphate, salt and iron, with ammonium citrate, a sugar, saccharin, alcohol and water. Misbranded because labeling failed to warn sufficiently against use by children, to whom it might prove dangerous to health, or against unsafe dosage or methods or duration of administration for protection of users since label did not caution that frequent or continued use of the product might result in dependence on laxatives. Further misbranded because label warning against using preparation when symptoms of appendicitis are present was not sufficiently conspicuous to make it easily read by the ordinary individual. Again misbranded because name "Fernol" and statements on the label falsely suggested that the article was an appropriate and effective treatment for obesity. Also misbranded because label declaration of contents failed to reveal the material fact that the effect of the mixture was due essentially to its epsom salt and that the other ingredients mentioned were present in relatively inconsequential amounts and that some of them, namely, sodium chloride (common salt), iron and ammonium citrate, saccharin, dextrose (grape sugar) and caramel color (burnt sugar) were not active ingredients.—[D D N J, F D C 615 February 1943]

Prostatic Absorbent—C. F. Breitenbach (Mucine Company), Chicago. Composition ichthammol, juniper oil and extracts of plant drugs incorporated in wool wax (lanum). Misbranded because of various false representations such as soothing and relieving chronic conditions of the prostate and bladder neck. Further misbranded because label failed to bear name and place of business of manufacturer, packer or distributor since designation "Ainsworth Specialty Co., Kansas City, Mo.," did not make clear this concern's connection with the product, and because label did not give the common or usual name of each active ingredient or its quantity. Also misbranded because label did not contain adequate directions for taking or sufficient warnings against use by children, or in those pathologic conditions in which it might be dangerous to health or caution against unsafe dosages or methods or duration of administration or application, for protection of user.—[D D N J, F D C 436 September 1942]

Prunlax—Adams Laboratories Inc., St. Louis. Shipped between Oct 11 and 14 1940. Composition essentially extracts of plant materials including laxative plant drugs with sugar, glycerin, flavoring materials and water, preserved with salicylic acid. Misbranded because label directions for adults and children were neither appropriate nor adequate, because label failed to caution against use by children, or in those pathologic conditions wherein it might be dangerous to health, or warn against unsafe dosage or duration of administration, for protection of users, since label did not caution the user that Prunlax was not to be taken in cases of appendicitis and that frequent or continued use might result in dependence on laxatives. Further misbranded because name "Prunlax" falsely implied that the product was derived from prunes, which it was not. Also misbranded because of misrepresentation that the absence of phenolphthalein and alcohol from the formula was evidence that the product contained no potentially harmful or deleterious ingredients, when such was not the case. A few other charges of misbranding also were cited.—[D D N J, F D C 452, September 1942]

Starr's Wonderful M. L. & K. Pills—Starr Medicine Company, San Francisco. Shipped April 1, 1941. Composition essentially extracts of plant drugs, including laxatives, with coating of calcium carbonate. Misbranded because label failed to warn adequately against use in those pathologic conditions wherein the product might be dangerous to health and against unsafe duration of administration, since the label failed to caution that the product was not to be taken in the presence of symptoms of appendicitis, such as nausea, vomiting or abdominal pain, or that continued use might result in dependence on a laxative. Misbranded also because label failed to give adequate directions for use as a laxative. Further misbranded because of false and misleading label claims, since the product contained no ingredients which would constitute treatment for conditions quoted. Used in weak back, liver kidney complaints, biliousness, cold, fever, headaches, indigestion. Also misbranded because label did not accurately declare quantity of contents.—[D D N J, F D C 555 November 1942]

Velpaus Pills—F. W. Briggs and Company, Buffalo. Shipped June 1 1941. Composition essentially aloes, ferrous sulfate, myrrh and starch with volatile oils, including sassafras oil, and a coating of sugar and chalk. Misbranded because directions on carton and in circular were not appropriate for the administration of a laxative. Also misbranded because labeling failed to warn against use in those pathologic conditions wherein it might be dangerous to health or against unsafe dosage or methods or duration of administration for protection of users since warning in circular failed to state that product should not be taken in the presence of symptoms of appendicitis, such as vomiting, nausea or abdominal pain and that frequent or continued use might result in dependence on a laxative. Further misbranded because not effective as represented, delayed menstruation even when taken under medical supervision and also because the warning to avoid all laxatives in case of symptoms of appendicitis did not reveal that this treatment itself is a laxative.—[D D N J, F D C 557 November 1942]

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts Cerebral Hemorrhage Resulting in Partial Paralysis Following 16 Inch Fall—
A man of 63 had had a high blood pressure condition which had been reduced to a normal range sometime before the industrial accident occasioning the litigation here discussed. In the course of his employment as a general repair man in the oil fields he was using both hands in tightening a nut on an eccentric power when the wrench he was using slipped from the nut, causing him to fall backward from the concrete platform on which he was working to the ground some 16 inches below. In falling he struck a pipe with his back. He noticed immediately that his back had been slightly injured and that his left foot had become numb and that his left toe was dragging. He went home immediately and has not been able to work since. That night he vomited. The next day his condition was worse and he consulted a physician. He grew worse and several days later was sent to a hospital eventually losing complete control of his left leg. Attributing his condition to the industrial accident, he instituted proceedings under the Oklahoma workmen's compensation act. At the hearing the medical witnesses were in agreement that Ale had a partial paralysis caused by a cerebral hemorrhage and that this was the proximate cause of his disability. The industrial commission found that the fall sustained in the course of Ale's employment had aggravated a preexisting condition and brought on the cerebral hemorrhage which resulted in partial paralysis. An award of compensation was accordingly made in his favor. The employer and his insurance carrier then instituted an original

proceeding in the Supreme Court of Oklahoma to obtain a review of the award.

The petitioners contended that the finding by the commissioner that the workman's paralytic condition resulted from the accidental injury he sustained from the fall was without the support of any competent evidence. The court then undertook to discuss some of the evidence before the commission. None of the physicians, said the Supreme Court, who testified at the hearing testified directly or positively that in their opinion the hemorrhage and the resulting paralysis were caused by the fall but, on examination of the medical testimony coupled with the time of the injury, the inferences and circumstances of the disability we must conclude that the commission had some substantial evidence on which to base an opinion that the fall was at least a contributing cause of the hemorrhage. The medical testimony is to the effect that there are four possible conditions which may give rise to a disability of the nature here involved: (1) strain (2) stress (the fall), (3) anger and (4) advanced years in general. There is no evidence of the presence of any of these conditions except the fall and the age of the workman. Dr Wilkins, who was called as a witness by the employer and his insurance carrier, stated:

Generally we just think if he had marked symptoms at the time he fell down then you would say this fall precipitated it that maybe it didn't cause it entirely but at least was the precipitating factor.

With respect to the existence of "marked symptoms" at the time he fell, the workman's testimony as to what happened after the fall is significant. He stated that he first walked to his car, which was about 50 feet away, and that his left toe was practically dragging on the ground. The first marked symptom then was present immediately after the fall. Again, Dr Wilkins testified:

yet there is a sufficient chain of events from that period (that is the time of the fall) to cause me to say that I am just not able to divorce the man's cerebral condition entirely from the strain and all of falling. Certainly had he not had the high blood pressure and the diseased vessels I don't think that fall would have done anything at all.

On direct examination Dr Wilkins stated that he was not able positively to say that the strain or the fall had anything to do with the cerebral hemorrhage. On the other hand on cross examination he stated that he would not say that the fall didn't cause the disability. This physician, continued the court was not called on to testify, one way or the other, as to the positive cause of the disability and in fact under the circumstances of the case, it would have been impossible for an honest physician, such as this witness appeared to be to have given a positive answer. The practice of medicine is not an exact science and especially so in regard to the human brain. Summing up the testimony of Dr Wilkins however, we believe the commission was justified in concluding that his testimony as a whole was to the effect that he could not account for the workman's condition other than connecting it with the fall. His evidence was really more convincing and more worthy of belief than it he had stated that the disability was or was not caused in whole or in part by the fall. Under all the facts and circumstances surrounding this case the commission had proper grounds to find a causal connection between the fall and the workman's present disability. A finding of fact of the industrial commission on nonjurisdictional grounds when supported by any competent evidence is conclusive on this court.

The award in favor of the workman was accordingly in effect affirmed.—*Tidewater Associated Oil Co v Ale* 130 P (2d) 991 (Okla 1942)

Pharmacy Practice Act (Oregon) Limitation of Sale of Aspirin to Licentiates of Board of Pharmacy Valid—A section of the Oregon pharmacy practice act (58-307 O C L A) authorizes the board of pharmacy to license shopkeepers not druggists to sell simple United States Pharmacopeia National Formulary and New and Nonofficial Remedies substances or preparations not of a poisonous nature in the original unbroken packages only and prohibits the sale of such substances except by licensed shopkeepers or licensed pharmacists. The section provides however that no license is required to sell certain articles such as olive oil glauber salts vaseline

carbonate of soda, borax, witch hazel, epsom salt "and other such articles and items as may hereafter be specifically listed, enumerated and exempt from the provisions of this act by proper order and regulation of the board of pharmacy," provided such products shall be sold in unbroken packages only. The defendant who operated a store and who was not a licensed druggist or a licensed shopkeeper, was convicted in a justice's court of the crime of selling a package of aspirin tablets without having obtained a permit or license from the board of pharmacy, and his conviction was upheld on appeal by the circuit court, Wheeler County, Ore. The defendant then appealed to the Supreme Court of Oregon.

The United States Pharmacopoeia, the National Formulary and New and Nonofficial Remedies, said the court, are official publications, of which this court may take judicial knowledge. The pharmacy practice act itself takes cognizance of those publications. Acetylsalicylic acid—commonly known as aspirin—is recognized as a drug or medicine in the official publication of the United States Pharmacopoeia, ed 12, pp 13, 14 and 15. Aspirin is not an entirely harmless drug or medicine, especially when taken in excessive doses. Undoubtedly the sale of medicines is a business subject to regulation under the police power by legislation reasonably necessary to protect the public health and morals. The mere fact that aspirin is a simple household remedy does not preclude the regulation of its sale. As was said in *State Board of Pharmacy v. Matthias*, 197 N Y 353, 90 N E 966:

There are strong reasons relative to the public welfare which make it proper that regulations concerning the sale of drugs and medicines should not be confined to poisons but may be extended so as to embrace what are known as harmless household remedies—that is, which may be harmless if properly prepared. The injury to the public health which might ensue if such medicines were carelessly or ignorantly compounded so as to contain deleterious ingredients or deceptively, so as to be something different from what they purported to be, is manifest. The police power logically extends to such medicines no less than to poisons and other lethal medicinal agents.

Of course, the regulations relative to the sale of medicines cannot be arbitrary or capricious but must have some reasonable relation to the end to be attained, namely the protection of the public.

The defendant first contended, in effect, that the board of pharmacy acted arbitrarily and unreasonably in classifying aspirin—a simple household remedy—as one which could be sold only by a duly licensed person. In other words, the defendant argued that by thus restricting the sale of aspirin the welfare of the public is not subserved. The court, however, did not agree with this contention. We see no unlawful delegation of legislative authority to the board, said the court, in this case. The legislature itself classified aspirin as a medicine which may be sold only by a duly licensed person. Its status as a drug or medicine was fixed by the legislature in view of the fact that it is a simple United States Pharmacopoeia and National Formulary remedy and is not within the exempted class of drugs or medicines enumerated in the act. Neither has it been shown that the board, in the exercise of its discretion, has seen fit to add aspirin to those medicines or drugs exempted from the operation of the act. As a matter of fact, the board in a regulation promulgated by it specifically prohibited the sale of aspirin except by licensed pharmacists and by licensed shopkeepers. That regulation is merely declaratory of the statutory classification of aspirin and was wholly unnecessary, since it is clear that the pharmacy practice act specifically makes it a crime for a person not a licensed shopkeeper or a licensed pharmacist to sell aspirin.

The defendant next contended that the pharmacy practice act for the violation of which he was convicted is unconstitutional in that the restriction relative to the sale of aspirin is arbitrary and unreasonable. If, said the court, the provisions of the pharmacy practice act are in fact arbitrary and unreasonable and bear no reasonable relation to the public health, their enactment and enforcement is not a valid exercise of the police power. Under the due process clause of the constitution no person can be arbitrarily or unreasonably restricted in the transaction of legitimate business. However, the constitutionality of similar statutes regulating the sale of drugs and medicines has been sustained in other jurisdictions. For instance,

in *State v. Hootworth Co*, 184 Minn 51, 237 N W 817, the court upheld the constitutionality of an act restricting to licensed pharmacists the sale of milk of magnesia. In disposing of the contention that such restriction was arbitrary and unreasonable, the court said:

We are not prepared to say that having a licensed pharmacist in charge of the sale of medicines, even if harmless and sold in original packages has no reasonable relation to public health and cannot be of public benefit.

Is it continued the court, arbitrary and unreasonable for the legislature to prohibit the sale, except by licensed pharmacists and licensed shopkeepers, of aspirin? If there is any reasonable basis which the court can conceive for such regulation it must be sustained as a valid exercise of the police power. The pharmacy practice act authorizes the board to employ inspectors to investigate all complaints as to the quality and strength of all pharmaceutical preparations and medicines and to take such action as may be necessary to prevent the sale of such as do not conform to the standard and tests prescribed in the official publications noted in the statute. Such inspection undoubtedly would aid in guarding against the sale of impure drugs and medicines. It would also enable the board to ascertain whether aspirin was being sold in standard doses. We think it is highly proper for the board, acting for the welfare of the public, to know who is dealing in drugs and medicines and such knowledge can best be obtained by requiring dealers to procure a license. The act does not discriminate against certain classes of shopkeepers, as all who obtain a license may sell aspirin. The grievance of the defendant—reduced to its ultimate analysis—is that the board failed to add aspirin to the list of drugs and medicines exempt from the operation of the act.

The court concluded that there was a reasonable basis for the legislation in question, as the regulation of the sale of the drugs in question tended to promote the public health. The judgment of conviction was therefore affirmed—*State v. Combs*, 130 P (2d) 947 (Ore., 1942).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 10 days to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents in one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be claimed for permanent possession only from them.

Immunity to Tetanus—Two years after the completion of basic immunization with two 0.5 cc doses of combined alum precipitated diphtheria and tetanus toxoids Peshkin gave to 31 allergic children a third or booster dose of 0.5 cc. (16 children received combined alum precipitated toxoids and 13 children alum precipitated tetanus toxoid alone). Antitoxin levels were determined at various intervals after the second and after the third dose of the toxoid and the respective totals of 159 and 194 specimens of blood serum were titrated for

tetanus antitoxin. The incidence of local reactions after the third dose of combined toxoids after the third dose of tetanus toxoid alone and after the basic immunization was 50, 25 and 25 per cent respectively. An elevation of temperature which lasted from one to two days occurred only after the third dose of combined toxoids in 22 per cent of the children. This incidence of febrile reactions contrasts with 3 per cent in the group of 65 children given a third injection of combined toxoids from three to fifteen months after basic immunization and with 1 per cent in the group given only the basic immunization. The injection of a third or "booster," dose of combined alum precipitated diphtheria and tetanus toxoids and alum precipitated tetanus toxoid alone into allergic children two years after the completion of basic immunization with two doses of combined toxoids was followed within one month by an adequate tetanus antitoxin titer which was always higher and lasted for a much longer period than that which followed basic immunization as well as that which followed the third dose of combined toxoids given from three to fifteen months after basic immunization. The antitoxin titer obtained on the seventh day after the third injection of toxoid given two years after basic immunization was always adequate and at its maximum in the majority of instances. Comparison of the initial antitoxin levels and the corresponding titers one month and two years after administration of the booster dose of toxoid for one group of children two years after basic immunization and for another group from three to fifteen months after immunization and for a final group given basic immunization only revealed not only that the percentage of the first group of children attaining the highest antitoxin levels (0.5 to 1 unit or more of antitoxin) within one month of receiving their last dose was significantly higher than that of either of the last two groups (100 compared with 70 and 32 per cent respectively) but that two years later the ratio between the patients of the three groups who showed an antitoxin titer of 0.1 unit or more was 4:1 (72 and 18 per cent respectively) for the children of the first and the second groups and 8:1 (72 and 9 per cent respectively) for the children of the first and the third groups. When a child has had basic immunization with two doses of combined alum precipitated diphtheria and tetanus toxoids and a third, or booster, injection of toxoid is administered two years later, then alum precipitated tetanus toxoid alone should be used in order to keep febrile, local and systemic reactions at the minimum.

Roentgenologic Changes in Small Intestine in Presence of Hookworm—Krause and Crilly show that infection with the hookworm *Necator americanus* causes alterations in the small intestine which they designate as the deficiency pattern. If this pattern is seen the stools should always be examined for the ova of intestinal parasites. The authors studied the small intestine of 97 young white men who had known to harbor *Necator americanus* and who had no other diseases known to cause the deficiency pattern. Of the 44 patients with

clinically significant "hookworm disease," 40 showed the deficiency abnormalities which were moderately or far advanced in 26. Of the 53 patients with asymptomatic, incidental hookworm infection, 33 had a normal small intestine, 16 showed minimal variations from the normal and only 4 had severe alterations of the normal pattern. After anthelmintic therapy alone there was a return toward, but not to, the normal pattern in those with severe involvement. Minimal alterations disappeared entirely in some instances. A significant correlation exists between the presence and extent of the physiologic alterations seen on the roentgenograms, the clinical findings and the severity of the infection with the hookworm.

Prevention of Hypoglycemic Symptoms—According to Thorn and his associates ingestion of a typical American breakfast—one relatively high in carbohydrate and low in protein and fat content—predisposes to midmorning hypoglycemic symptoms. The prolonged sense of well-being which follows the ingestion of a meal rich in protein suggested that the intake of increased protein at breakfast might obviate the necessity for midmorning nourishment and might be expected to improve the performance of individuals who do not have access to supplementary nourishment at that time. Studies were undertaken to determine the changes in blood sugar level, caloric distribution and metabolic rate which followed the ingestion of isocaloric breakfasts composed of varying proportions of carbohydrate, fat and protein. In a normal subject the ingestion of a breakfast high in carbohydrate and low in protein and fat was followed by hypoglycemic symptoms in one to two hours, an isocaloric breakfast high in fat and low in carbohydrate and protein was followed by hypoglycemic symptoms at a later hour, an isocaloric breakfast high in protein and low in fat and carbohydrate was followed by an improved sense of well-being and no symptoms of hypoglycemia. The blood sugar levels following these three types of breakfast correspond closely to the clinical symptoms. A sustained increase in metabolic rate occurred following the ingestion of the high protein breakfast, a transient increase in metabolic rate followed by a fall below the basal metabolic rate was observed after the ingestion of an isocaloric high carbohydrate breakfast, no significant increase in metabolic level followed the ingestion of an isocaloric high fat breakfast. Following the ingestion of the high carbohydrate breakfast, differential derivation of calories reflected striking fluctuations in the character of the food substances utilized as sources of energy. These fluctuations did not occur following the isocaloric high protein and high fat meals.

Immunity in Mumps—Enders found that infection of the rhesus monkey with the virus of mumps leads in a short time to the appearance of specific complement fixing antibodies which are not present in normal susceptible animals. These antibodies may persist in the blood for many months. Serums from

patients with mumps at comparable periods of the disease have given results analogous to those noted in the animal experiments. In man as in the monkey, specific complement fixing antibodies are usually absent in the earliest stage of the disease, appear shortly thereafter, increase and then decrease to persist for at least some months following recovery. These observations have led to the application of the test as an aid in the diagnosis of cases of encephalitis without definite parotitis, suspected on clinical grounds of being attributable to infection with the virus of mumps. It became of great interest to ascertain whether the complement fixing antibody was present or absent in the serums of normal individuals, since its presence might be taken to denote previous infection with the virus whether or not this had led to clinically apparent disease. Conversely, its absence might be assumed to indicate susceptibility. The author presents results of studies on 163 persons at the Harvard Medical School. Antibodies occurred in about 92 per cent of the serums of those giving a positive history of mumps. In sharp contrast, 50 per cent of the serums of those who denied having had the disease contained antibodies. Thus it seems possible that nearly half of those who denied having had mumps underwent an inapparent or "silent" infection which should render them insusceptible. On the other hand, it seems that those in whose serums antibodies could not be demonstrated are potentially susceptible. The experiments with the children yielded data of the same sort, but, as could be expected in this age group, the percentage of negative reactors with negative histories was greater. The author developed a skin test which was positive in cases with a history of mumps and in which the complement fixation test was negative. The results strongly imply that a positive skin reaction indicates a previous infection with the virus, whereas failure to react signifies in most instances potential susceptibility.

Treatment of Surface Burns—A feature of the treatment of the 39 burned patients brought to the Emergency Ward of the Massachusetts General Hospital from the Coconut Grove night club consisted in omission of debridement and cleansing. Gauze strips saturated with a bland ointment (boric acid) were applied to burned surfaces and kept in place with pressure bandages. Two Gm. of sodium sulfadiazine was injected intravenously through the cannula or needle already in place for plasma transfusion. The dressings were not changed until the fifth to tenth day, when boric acid ointment gauze was reapplied. A major point in favor of nondebridement of the burn is the availability to the wound of chemotherapeutic agents administered internally. Absorption of sulfonamides applied locally to the debrided burn surface may be rapid and irregular and, if the burn surface is large, toxic levels of the drugs in the body fluids may be reached. The levels of the sulfonamide drugs in the body fluids are more easily controlled by internal administration. The advantage of the treatment lies in its simplicity. The available personnel is freed for the care of shock and anoxia, yet the surface wounds need not be neglected.

Leukemia Studies on 123 Fatal Cases—Kirschbaum and Ireuss correlate clinical and pathologic observations in all types of leukemia. They examined 123 fatal cases which were selected from 14,400 consecutive autopsies. The cases are classified in three ways: (a) according to the clinical course as acute leukemia or chronic leukemia, (b) according to the type of cell in the peripheral blood, bone marrow and tissues as stem cell leukemia (28 cases), myelogenous leukemia (53 cases), lymphatic leukemia (37 cases) and monocytic leukemia (5 cases) and (c) as leukemic or aleukemic disease. Of the patients 69 per cent were male, 30.1 per cent were female, 78 per cent were white and 22 per cent were Negro. The high incidence of acute leukemia in the older age groups is unusual. Stem cell leukemia occurs most frequently in persons in the first three decades. Enlargement of the liver and the spleen was most commonly encountered in myelogenous leukemia and less frequently in lymphatic leukemia and stem cell leukemia. Definite anemia was observed in all forms of leukemia. The white blood cell picture showed considerable variability and fluctuation. Attention is drawn to the observation that grave leukopenia may be observed in the early or the late stages of stem cell leukemia and myelogenous leukemia especially in the acute forms. Advanced thrombopenia may cause a hemorrhagic diathesis. Myeloid metaplasia was frequently noted in myelogenous leukemia and stem cell leukemia. Repeated transfusions of blood produced the most beneficial results but gave only temporary relief.

Electroencephalographic Foci Associated with Epilepsy—According to Gibbs and his collaborators the problem of diagnosis and treatment of epilepsy often centers on the question of whether or not localizing signs are present. Electroencephalographic evidence of a focus of abnormal activity is an important localizing sign. In 174 cases (15 per cent) of a total series of 1,161 cases of epilepsy studied at the Boston City Hospital there were found either localizing symptoms or signs on neurologic examination or an electroencephalographic focus. The presumed cause of seizures in these 174 cases was trauma in 69 cases, infection in 20 cases, vascular disease in 14 cases, birth injury in 12 cases and developmental defects in 4 cases. In 55 cases there was no evident cause for the seizures. In

58 per cent of the 160 cases with electroencephalographic foci clinical localizing signs were present, and in all the clinical and electroencephalographic localizations were in agreement. A corroborating electroencephalographic focus was noted in 87 per cent of 106 cases with clinical localizing signs or symptoms. Clinical evidence of localized damage to the brain was fifty-eight times as common in epileptic patients with electroencephalographic foci as in patients in whom the disturbance was generalized or absent. The same types of seizure discharge or other electroencephalographic abnormality were encountered in cases with focal electroencephalographic activity as in cases with nonfocal disorders. However certain types of abnormality notably irregular 1/2 to 3 per second activity spikes and 2 per second waves and spikes were much commoner in focal than in nonfocal records. The presence of one of these three types of abnormality is presumptive evidence of localized damage to the brain.

Chronic Granuloma Following Typhoid Vaccine—Tilden and Arnold observed a peculiar hitherto undescribed, focal granulomatous reaction to intradermal injections of triple typhoid vaccine in 6 among a total of 4,500 vaccinated persons. The vaccine employed was prepared by the United States Army using the Bovill strain. No correlation appears between the reaction and previous injections of typhoid vaccine. It is not known whether this reaction vitates the effect of the vaccination or not. Its chief practical importance appears to lie in the possible cosmetic consequences should the vaccination be performed in a conspicuous location. The observation is of theoretical importance because it so clearly demonstrates the similarity between the histocytic response to injections of triple typhoid vaccine and the histocytic response to virulent typhoid bacilli and because it constitutes another link in the growing chain of evidence that spindle-shaped cells in granulation tissue may be histocytes and not as is so often and so easily assumed fibroblasts.

Diverticulosis and Diverticulitis of Colon—Kilfoyn shows that with modern roentgenology the diagnosis of diverticulosis and diverticulitis is common and that these conditions occur in 5 to 15 per cent of the general population after the fourth decade of life. In about 5 to 10 per cent complications develop and 12 to 20 per cent require surgical intervention. These diverticula do not exist at birth but occur in the fourth, fifth sixth and seventh decades of life. They are more frequent in males than in females the ratio being about 2:1. They are produced by many extraneous factors such as obesity, constipation, flatulence and weakness in the longitudinal muscle fibers of the colon. Most patients can be kept well on a smooth, high caloric diet. To keep the lower bowel evacuated enemas are advisable or liquid petrolatum or any other soft oily preparation may be given by mouth. The patients must always watch their diet and be educated to watch for complications. If there is severe pain high leukocyte count, tenderness, rigidity and evidence of perforation or of abscess formation, immediate surgical intervention is indicated. In a large percentage of cases the clinical diagnosis will be either acute appendicitis or ruptured duodenal ulcer. Many methods of surgical attack have been suggested. A single diverticulum can be excised. Resection of the colon or of the area involved may give good results.

Immersion Blast Injuries of Abdomen—Webster and his associates observed 15 survivors of a torpedoed ship who sustained abdominal injuries from an exploding depth charge while swimming. They were swimming away from the ship but turned to watch it as it dived and were facing it when the explosion occurred. Each felt that he had been struck a tremendous blow in the abdomen. All suffered severe abdominal pain, crampy in some but mostly a pronounced stabbing pain. All vomited repeatedly, several with blood and bile, and 9 had bloody diarrhea. All had fever averaging 102 F. In 5

distention developed, and almost all had rigidity of the abdominal wall. Four patients died. Four after a protracted convalescence still had mild symptoms five months after the injury. Seven recovered in from three to fourteen days. The tremendous force of the blast is proved by the fact that a cigarette lighter and a wrist watch carried by an officer were completely flattened. He was swimming on his back beside his captain, who was swimming on his abdomen, when the blast occurred. The captain was killed. The officer survived, with the usual symptoms of vomiting, bloody diarrhea and pain, and was able to leave the hospital in two weeks. This seems to argue against the suggestion that the blast enters the rectum. Thoracic symptoms were almost completely absent. Almost all these men had kapok life preservers about their chest, which probably gave protection as well as elevating them to the water's surface. The leukocytosis, the prolonged sedimentation rate, the fever, the loss of weight associated with moderate or severe abdominal pain, tenderness and rigidity, and the absence of physical signs of abscess formation suggest a low grade inflammatory process. It is possible that injury from submucosal hemorrhages permitted pathogenic organisms to infiltrate or pass through the wall of the bowel. The apparent response of two of the patients to sulfathiazole would support this assumption. Submucosal and petechial hemorrhages in the bowel wall could interfere with the neuromuscular mechanism, producing ileus, late sloughing and perforation. The authors recommend that naval personnel be warned of this danger, that life preservers be made of kapok and designed to cover the abdomen and chest, and that physicians in coastal areas appreciate the urgency of early treatment, both medical and surgical.

Effect of Riboflavin on Cornea Vascularization and Eye Fatigue—Tisdall and his collaborators attempted to demonstrate photographically the changes which occur in the cornea in riboflavin deficiency. Kruse and his co-workers had suggested that the minor degrees of vascularization of the cornea frequently seen in apparently normal human beings were due to a deficiency of riboflavin. They postulated that symptoms of tiredness of the eyes, burning of the eyes, a sandy sensation under the lids and lacrimation might be manifestations of the deficiency and might be cleared by the administration of riboflavin. Riboflavin is rapidly destroyed by light, and it seems possible that a person who is exposed to a great deal of light would have an increased destruction of riboflavin in the eye which would necessitate a greater intake to maintain normal vision and normal health. Men in the Air Forces are exposed to much light. The authors investigated the various degrees of vascularization of the cornea in men who were flying over water and exposed to considerable glare. One hundred and ninety-eight men were examined. There was only 1 man with normal eyes, 17 showed stage 1 involvement, 87 stage 2 and 93 stage 3. A group of men showing stage 3 involvement was chosen to demonstrate the effect of treatment on vascularization of the cornea and the symptoms of fatigue of the eyes. These men were questioned regarding tiredness of the eyes, aching of the eyes, watering of the eyes, sandy sensation under the lids, dizziness, headaches, intolerance of reading and decreased visual acuity. Sixty-seven per cent suffered two or more of these symptoms. The men were divided into three groups. One received capsules containing 33 mg of riboflavin three times daily for a period of two months. The second group received similar capsules three times daily for one month. The third group received capsules which were similar in appearance but which contained no riboflavin. Of the 28 men who received treatment with 99 mg of riboflavin daily for two months, 20 showed either pronounced or moderate improvement, 8 showed either slight or doubtful improvement or no change and none showed increase in vascularization of the cornea. Of the 21 men who received treatment for a period of one month, 6 showed pronounced or moderate improvement, 14 showed slight or doubtful improvement or no change, and 1 man showed an increase in vascularity. Of the 21 men treated with placebo, none showed either pronounced or moderate improvement, 15 showed slight or doubtful improvement or were unchanged, and 6 were worse. In areas where milk, the best source of riboflavin in the diet, was not available, the prevalence and the severity of corneal vascularization were increased.

Determination of Rate of Thyroid Hormone Secretion at Various Environmental Temperatures E W Dempsey and E B Astwood—p 509

Secretion of Thyroid Hormone at Various Temperatures—From data presented by Dempsey and Astwood it may be concluded that the rate of secretion of the thyroid hormone is increased by exposure to cold and reduced by exposure to heat. The maintenance or restoration of normal thyroid weight by the administration of thyroxin to rats simultaneously treated with the antithyroid drug thiouracil has been used as the basis of a procedure for the assay of thyroid hormone. The rate of thyroid enlargement in response to thiouracil was low in hot environments and high when rats were maintained in the cold. A quantity of thyroid hormone equivalent to 52 micrograms of thyroxin daily was required to maintain a thyroid of normal weight in young male rats kept at room temperatures averaging 25 C. At 1 C the thyroxin requirement was increased to 95 micrograms while at 35 C it was decreased to 17 micrograms. These values are considered to be quantitatively equivalent to the amount of hormone produced by the normal thyroid gland under these conditions.

Hyperventilation Syndrome in Aviation—Hinshaw and his collaborators describe the symptoms produced by voluntary deep and rapid breathing which are characterized by dizziness, blurring of vision, numbness of the extremities and in later stages by muscular cramps, serious vasomotor collapse and unconsciousness. These symptoms are produced by apnea and may result from spontaneous unrecognized hyperventilation occurring under conditions of emotional strain, excitement and anxiety. The symptoms of extreme hyperventilation are well known but it has not been adequately emphasized that similar ones are produced by mild hyperventilation continued over a longer period. Such symptoms would interfere seriously with a pilot's ability to control an airplane. A few instances of probable spontaneous hyperventilation among fliers have been described. The authors noted a clear variation in results produced among different aviators tested by voluntary hyperventi-

lation. The severity of symptoms was not related to the degree of acapnia produced. They propose that the demonstration of voluntary hyperventilation be included as a part of the routine periodic medical examination of commercial and military pilots so that these fliers may be trained to recognize the symptoms produced and to control them by voluntary suppression of respiration should they occur during flight. If this plan should be carried out on a sufficiently large scale it would be possible to determine how frequently spontaneous hyperventilation occurs during flight and to estimate its importance as a factor in the production of 'pilot error'.

Decompression Disease of Bone—Allan points out that during ascent in an airplane the tissues become supersaturated with nitrogen because the partial pressure of nitrogen in the lungs falls off. As this pressure is released the nitrogen comes out of solution in the body and appears in the tissues and in the blood in the form of bubbles. Since the elimination of nitrogen from the body is entirely through the blood stream those parts of the body which have the poorest blood supply will be the slowest to lose their excess nitrogen. Bone is the tissue with the poorest blood supply in relation to the nitrogen content. There are two areas in bone where anastomotic connections are limited, namely the epiphyseal area and the metaphyseal area close to the epiphyseal line. In these two areas the reaction to complete or incomplete interruption of the blood supply is the same as in any area with limited anastomotic connections and the process is known as aseptic necrosis. In these two areas are found the lesions so characteristic of decompression disease of bone. The favored seats for these lesions are the long bones, the shoulder joint and the hip joint. The late effects of this process are recognizable roentgenographically. They are (1) aseptic necrosis of the hips and the shoulders, (2) medullary calcification in the diaphyseal ends of the long bones and (3) hypertrophic arthritis. Not all of these need be present to justify the diagnosis. Aseptic necrosis with osteoarthritis may occur without medullary calcification. Joint changes are more frequently present than changes in the long bones. The recognition of such bone changes is of paramount interest in time of war as the incidence of symptoms due to decompression illness associated with high altitude bombing and fighting are on the increase.

Present Status of Convulsive Shock Therapy—Bennett shows that convulsive shock therapy is of doubtful value in modifying the schizophrenic personality. In cases with affective predominance it is effective but otherwise it is not advisable in schizophrenia. The induction of grand mal seizures by whatever method is effective in a large percentage of affective disorders. Traumatic skeletal and visceral complications are extremely serious in any form of straight convulsive shock whether induced by a drug or electrically. Preliminary curarization is a safe preventive of traumatic complications in any type of convulsive shock. It increases the scope of usefulness of convulsive therapy and lessens the contraindications and thus improves the therapeutic results.

Pheochromocytoma of Adrenal Gland—Tumors of the medullary portion of the adrenal gland, according to Hyman and Mencher may be divided clinically into those which produce hormonal symptoms and those which do not. Tumors of the pheochromic cell (pheochromocytoma) represent the type producing the hormonal symptom complex, sympathoblastomas, neuroblastomas, and ganglioneuromas arising from the ganglionic cells represent the nonhormonal type of tumor. The pheochromocyte represents the mature stage of the endocrine differentiation of the formative cells. An abnormal proliferation of these mature cells leads to the development of hormonal medullary tumors variously known as chromaffinomas, paragangliomas or pheochromocytomas. These occur not only in the medulla of the adrenal gland but wherever chromaffin tissue is present. They may thus be intra-adrenal or extra-adrenal in location. They are usually benign and well encapsulated. In a typical history the patient begins to complain of a pounding headache, nausea, dyspnea, orthopnea, palpitation, blanching of peripheral portions of the body, paresthesias, abdominal cramps, vomiting, precordial throbbing and extreme weakness. The attacks vary in length from minutes to hours, during which time the patient may be in a state of shock. The attacks usually terminate with flushing of the blanched areas, profuse perspiration and weakness. Death during an attack may occur from shock, pulmonary edema, failure of the left side of the heart, coronary disease or cerebral manifestations. The attacks may occur spontaneously or they may be induced by any mechanism which calls forth a discharge of epinephrine (pressor response). The causative factors include emotional upset, fear, anger, slight trauma, change in posture from the reclining to the upright position, physical exertion, hyperventilation, lying on the side of the tumor, massage of the abdomen on the side of the tumor, administration of histamine or of epinephrine or immersion of the extremities in cold water. The diagnosis of pheochromocytoma is based on (a) the typical symptom complex during an attack (spontaneous or induced), (b) the typical mechanisms of a pressor response, (c) the demonstration of a pressor substance in the blood of a patient during the height of an attack, (d) the demonstration of the tumor by perirenal insufflation. Four cases of pheochromocytoma of the adrenal gland are presented. Three of the patients were women and the fourth was a male. All the tumors were removed successfully and all the patients made an uneventful recovery. A long period of follow-up reveals that the patients are in excellent health and that no further attacks have occurred.

Ultimate Results of Transurethral Prostatic Resection—Orr and his co-workers made a follow-up study of 483 cases of transurethral resection of the prostate. Of these 407 were traced. One hundred and fifteen patients died within a few months to nine years or more after leaving the hospital. Intelligible replies were received from 252, and of

this number 209 presented themselves for examination. The information obtained did not substantiate the extremely low mortality rate reported by other workers with the method. Patients who stated that they were completely relieved and in whom a complete resection had been performed had no evidence of regrowth on cystoscopic examination several years after operation. Complete resection implies the removal of all obstructing tissue down to the fibers of the prostatic capsule in all directions in all quadrants of the vesical outlet. Patients who returned with obstructive symptoms years after the original operation were invariably found to have hypertrophy in that part of the prostate which was not interfered with at the original operation. Patients who were never completely relieved and who returned a few months to a year later were usually those from whom not enough prostatic tissue had been removed. Persistent pyuria resulting in frequency, burning and nocturia has been a discouraging complaint in a large majority of cases. Pathologic as well as bacteriologic study of the tissue removed indicates that pyuria is far more often due to the leaving behind of infected bits of prostatic tissue than to the introduction of infection during or immediately after the operation. The pathologist is at a disadvantage in making a diagnosis of the tissue removed by resection unless practically every section is examined. In many cases incipient carcinoma is undoubtedly overlooked, as evidenced by the number of patients returning with unmistakable signs of a cancerous process in later years. Many of these patients would have stood a much better chance of cure had they undergone total prostatectomy. The most important conclusion to be gained from this study is that a great many more patients with severe organic diseases were given the opportunity for relief of their urinary obstruction by the use of transurethral resection where other methods of removal may have been considered too hazardous. It is in this narrow field of borderline patients that prostatic resection offers an advantage over other methods of prostatectomy.

Varicose Ulcers of Leg—Manning stresses the need for more standardized methods of treatment of varicose ulceration. High saphenous ligation, with multiple ligations when indicated, accompanied by retrograde injection is the best method of obliteration. Periodic injections of isolated varices may easily be done during the follow-up treatment. Stimulation of granulation tissue should be undertaken following stoppage of the

reversed flow of blood. Removal of the stagnant tissue fluids about the ulcer can be accomplished by the use of an elastic supportive bandage. A most important point is that the patient should use the leg while the bandage is in place to obtain a better result. Skin grafting will occasionally greatly shorten the period of healing. Recurrences will be prevented in some cases by prolonged support.

Appraise Vitamin Formulas and Not Titles—To evaluate a vitamin combination it is necessary to know the amount of the vitamins it contains. For this reason their biologic activity should be expressed in terms of a common system and where possible the weights in milligrams of the vitamins should be given. The vitamins should be present in the ratio of the adult minimum daily requirement to permit adequate dosage of any component without waste of others. Five times the daily recommended allowances or maintenance levels should be pre-

scribed for therapeutic doses. It is also necessary to bear in mind the cost of the product on the basis of the daily cost of supplying the therapeutic requirements of the individual.

Prefrontal Lobotomy—Watts and Freeman have performed lobotomies on 136 patients during the last six years. Unless sufficient white matter is cut worry, nervous tensions, apprehension and obsessive thinking are not permanently relieved. The operation must be done symmetrically on both sides. Anatomic studies of patients who have died some time after the operation showed that integrity of the cortical architecture in the frontal lobe is preserved but that degeneration takes place in the nucleus medialis dorsalis of the thalamus. The authors believe that this bundle is of importance in linking ideational with affective experience and that interruption of this pathway is the greatest factor in producing alteration in emotional responses of the patient. Having observed repeatedly that a satisfactory therapeutic result occurs when lobotomy produces drowsiness, impairment of memory and disorientation they now use these as a yardstick to determine the depth and the extent of the incisions. Whenever possible the patient is operated on under local anesthesia. The neurologist converses with the patient and puts him through various intellectual exercises. Apprehension and anxiety may decrease or disappear after two or three quadrants have been cut but this is not enough. Unresponsiveness or disorientation is usually necessary in order to obtain a satisfactory clinical result. Disappearance of nervous tension, impairment of memory, confusion and disorientation usually come on within a few seconds to a few minutes after the fourth quadrant is sectioned. There is little shock associated with the operation. When prefrontal lobotomy fails to relieve the mental symptoms or when the remission of symptoms is only temporary, a second or even a third operation is performed. This has been done on 23 of the authors' patients. Twenty-seven of the patients subjected to prefrontal lobotomy are regularly employed, 16 are employed part time or studying and 39 are keeping house. Therefore 82 are leading useful lives. Thirty more are living at home but are not taking an active part in the activities there. The best results occur in the obsessive tension states and the involutional depressions. Definite conclusions cannot be drawn about the schizophrenias until more time has elapsed and a larger series is accumulated but the results have been satisfactory enough to encourage use of the procedure in selected cases.

Relief of Allergic Premenstrual Headache—Phillips points out that premenstrual headache may be accompanied by nausea, vomiting, vertigo and visual disturbances and frequently by pruritus or urticaria. Premenstrual tension is a condition of more or less irritability, emotional sleeplessness,

and temperamental change, may occur without a headache, but it also may precede the headache. Malaise, discomfort and eruptions on the face are not unusual. These manifestations vary widely in degree and duration. With the increasing employment of women in essential industries this recurring impairment of efficiency or absence from work presents a considerable industrial problem. The author found that certain allergic women who suffer from premenstrual headache, premenstrual tension and associated dysfunctional ailments were found to have sharply positive reactions to intradermal testing with a gonadotropic preparation, a 1:5 dilution of synipoidin (a combination of chorionic gonadotropin and pituitary extract). Numerous controls had a negative response. Women showing positive reactions were relieved by intradermal desensitization with the same preparation. This test and treatment are simple, harmless and effective. It is recommended for trial by gynecologists and industrial physicians.

Results in 155 Cases of Primary Atypical Pneumonia

—Correll and Cowan report clinical observations in 155 unselected clinically similar cases of atypical pneumonia, which may be classified as primary atypical pneumonia, etiologic agent unknown. The principal clinical symptoms were rapid onset with chilliness, intermittent or remittent fever lasting six to eight days, sore throat, nonproductive cough becoming productive in four to seven days, and headache. The physical findings frequently developed late, and the paucity of such findings as compared with the extensive x-ray findings was striking. Resolution as demonstrated by x-ray studies usually took about twenty days. The infrequency of complications and sequelae, the frequency of migration and delayed resolution and the failure to respond to sulfonamides were the other characteristics of importance. Not infrequently a febrile period of one to two days, with a temperature of 100 F, and a few findings

in the chest may prove on examination to be extensive pneumonia requiring twenty or more days for resolution. The proper x-ray technique is important in order to avoid overlooking this type of pneumonia. The x-ray films must be made with a so-called light technique, that is, the dorsal vertebrae should not be visible through the cardiac shadow. In 1 of 23 patients given x-ray therapy within four days after admission there was a failure to respond to treatment. In the remainder the febrile period, the total number of days of illness and the days for resolution as proved by x-ray examination were reduced one half. Of 9 patients whose pneumonia failed to resolve within thirty days on routine or other treatments, as evidenced by x-ray studies 7 showed x-ray clearing within an average of 40 days after one or two treatments of 112 roentgens each. Twenty-two and three-tenths per cent failed to be benefited by x-ray treatment. Roentgen therapy in this series showed definite promise in shortening the period of sickness in cases of acute development, it appears to be of definite value in shortening the period of delayed resolution and may be of aid in decreasing the incidence of complications. Its further trial in similar cases is suggested.

Primary Atypical Pneumonia—Haight and Trolinger present their observations in 47 cases. Although the disease does not seem to be highly communicable, its incidence may be much higher than is generally appreciated in view of its as yet limited recognition. The authors have found the following aspects of greatest value in diagnosis: (1) a benign clinical appearance, (2) a gradual onset with chilly sensations, head ache and malaise, (3) relative bradycardia—pulse rate out of proportion to fever, (4) suppressed breath sounds as the most reliable and localizing of the usually deceptive pulmonary signs, (5) an essentially normal hemogram and normal flora in the sputum and (6) an x-ray film of the chest as the final court of appeal, without which few cases can be definitely diagnosed. There were no complications (pleural effusion, empyema, secondary invaders, abscess, pleuritis or bronchiectasis) in this series. As the disease is apparently unaffected by the sulfonamides, treatment is symptomatic and supportive.

Local Use of Sulfathiazole in Treatment and Prophylaxis of Gonorrhea—Stedman employed the microcrystalline preparations of sulfathiazole because of the ease of application, the property of remaining in a milklike suspension and the absence of a tendency to clump and cake. He tried this therapy in a group of native women who were the source of gonorrheal infection in the military forces. Of 60 women who had been treated during the last three years, 17 were found to be infected. These were immediately started on local therapy consisting of daily douches of 5 per cent saponated solution of cresol followed by swabbing of the cervix and vagina with acriflavine 1:2,000. Five did not respond after three or four weeks of this form of therapy. These 5 who still had smears positive for the gonococcus and all others subsequently encountered provided the clinical material for a trial of local sulfathiazole therapy. The method of treatment was as follows: 1. Treatments were given once daily. The mucopurulent exudate was removed from the cervix and vagina with a dry sponge. 2. Three methods of application of microcrystalline sulfathiazole were used: (a) By means of a powder blower the cervix and vagina were coated with microcrystalline sulfathiazole, (b) 2 or 3 cc of a 5 per cent solution of microcrystalline sulfathiazole was instilled into the vagina or (c) a suppository of 10 per cent microcrystalline sulfathiazole was inserted into the vagina. This suppository takes about ten minutes to dissolve, spreads out over the entire cervix and vagina and remains for several hours. The glycerin suppository was found to be the best form of application. 3. About 5 cc of a 5 per cent suspension of microcrystalline sulfathiazole was instilled into the urethra. This plan of treatment resulted in negative smears in from eight to thirty-one days. Local sulfathiazole therapy caused the patients no inconvenience except the daily attendance at the "clinic." There was no evidence of irritation or inflammatory reaction due to the local use of the drug. Prophylaxis by urethral instillation of a 5 per cent suspension of microcrystalline sulfathiazole was effective in all but 2 (99 per cent) of 297 males. The use of vaginal suppositories of microcrystalline sulfathiazole is suggested as prophylaxis against gonorrhea in order to protect both parties of the sexual union.

Chronic Mastitis and Carcinoma—McKinley discusses the relationship of chronic cystic mastitis to carcinoma of the breast. He presents a summary of the pathologic pictures that come under the heading of chronic cystic mastitis as described and interpreted by Chertle and Cutler. The first is metaplasia the mammulation in the breast of excessive secretion of corpus luteum. The second form is cystiferous dequamous epithelial hyperplasia. Malignant neoplasia of the breast arises chiefly from the sessile papillomas. McKinley reviews 60 cases of chronic cystic mastitis seen in the University of Oregon Medical School and also the records of the cases of breast carcinoma of the tumor clinic. He found that 23 per cent of 128 pathologic reports of breast carcinoma contain an associated diagnosis of cystiferous dequamous epithelial hyperplasia or imply such a diagnosis. He thinks that this percentage is inaccurate and too conservative. In 4 per cent of the reports the carcinoma originated in papillomas of cystiferous dequamous epithelial hyperplasia. The analysis of the cases of cystiferous dequamous epithelial hyperplasia or chronic cystic mastitis has not resulted in a satisfactory appraisal of the incidence of subsequent carcinoma. Reasons for the inability to draw conclusions are that (a) too small a series has been accumulated, (b) many of those on whom the diagnosis is made clinically have not had pathologic confirmation and (c) follow-up has been too infrequent and too short. The author thinks that with regard to the management of an individual case of chronic cystic mastitis the attitude of Shields Warren seems the most logical. Chronic cystic mastitis predisposes to cancer. It is impossible to tell clinically in which case cancer will or will not develop. The risk is probably not sufficiently great to warrant bilateral mastectomy in all cases. Certainly all localized masses in the breast should be excised and examined but local excision will be followed by further symptoms in about 15 per cent and will not insure against carcinoma either microscopic at the time of surgery or in the future. Endocrine therapy (or pregnancy) may be permissible in those under 30.

Prostinine Pregnancy Test—Douglas directs attention to the prostinine pregnancy test first announced three years ago by Soskin Wachtel and Hechter. He reviews 62 cases of menstrual delay in which he resorted to the intramuscular injection of prostinine methyl-ulfate and concludes that this procedure is a reliable test for pregnancy and that it yielded results comparable to the Friedman test. In all instances in which the Friedman test was used to corroborate the prostinine test the two were found in perfect accord. In borderline endocrine cases the interpretation of the prostinine test must be as carefully guarded as in certain positive Friedman tests. In 2 instances in which this test was used in cases of dyscrinism prostinine failed to bring on the menstrual flow as might be expected. The clinician must not include such cases for a prostinine trial without properly evaluating the glandular factors involved. The advantage of prostinine as a test for pregnancy over that of other pregnancy tests is especially noted in that in the absence of pregnancy or a glandular dysfunction it will bring about vaginal bleeding thereby acting as a therapeutic as well as a testing agent and affording quick psychologic and physiologic relief. The test is simple the results are accurate and it can be applied by the clinician in his office.

Jaundice Following Administration of Human Blood Products—Morgan and Williamson describe a small series of cases of jaundice which followed the intravenous administration of plasma or reconstituted dried human plasma. The observation of jaundice in 2 patients who had received serum intravenously several weeks previously led to an investigation or all known to have been transfused with serum or plasma in the past year. Of 56 patients 50 have been traced and 9 (18 per cent) of them have since developed jaundice. Six were under direct observation at the time of jaundice but 3 were questioned retrospectively. The author gives brief histories of these 9 patients. There were no cases of jaundice among the medical and nursing staffs of the wards concerned. None of the patients who returned to their homes before developing hepatitis were aware of contact with any case of jaundice. The onset of symptoms which was sudden occurred forty-nine to one hundred and seven days after the last transfusion. Malaise nausea and epigastric discomfort which sometimes persisted for some weeks accompanied the jaundice in 7 cases and preceded its onset by a few days in 3. In all but 1 of the cases the liver was enlarged and tender but in only 1 was the spleen palpable. There was a positive direct van den Bergh reaction in 5 cases and pale stools in 7. The duration of the illness varied from three to twelve weeks. The clinical picture most closely resembles that of infective hepatitis. It seems unlikely that this is an outbreak of infective hepatitis.

The only common causal factor was the administration of serum or plasma. It therefore seems probable that these fluids are of etiologic significance and that this outbreak is similar to those occurring after yellow fever and measles inoculation. The recognition of such cases of jaundice with transfusion may easily be overlooked in view of the long symptomless period which intervenes.

Laboratory Diagnosis of Dysentery—According to Emlynson dysentery in the Middle East, as in South Africa may be caused by helminthic, protozoal or bacterial infection. He investigated 125 cases of dysentery in a South African General Hospital in the Middle East. Thirty-eight cases showed a 'bacillary exudate' diagnostic of bacillary dysentery. 57 cases showed an "indefinite exudate," while 30 cases showed no exudate. Eleven of the patients examined, or 8.8 per cent were found to be infected with *Endameba histolytica*. Three patients were found to be passing *E. histolytica* cysts. These patients all showed evidence of previous *E. histolytica* infection. Thirty-two of the 38 patients showing "bacillary exudate" yielded dysentery bacilli on culture. *Bacterium flexneri* was isolated in the majority of cases. *Bacterium shigae*, *Bacterium dysenteriae* Schmitz and *Bacterium sonnei* also were encountered. A routine examination of 55 suspected carriers yielded two cultures of *B. flexneri*, and in 1 case *Schistosoma mansoni* ova were identified. *B. flexneri* was isolated from 3 of 12 sigmoidoscope specimens obtained from patients with chronic dysentery.

Chemotherapy in Anaerobic Infections of Wounds—McIntosh and Selbie state that an analysis of cases of gas gangrene failed to show an appreciable reduction in its incidence in spite of prophylactic and therapeutic chemotherapy. They report the results of some further experimental investigations. A large number of chemotherapeutic substances were tested. It was found that the discrepancy between the experimental and field results seems largely due to the fact that most of the experimental anaerobic infections used as tests are not severe enough to be comparable with the disease in man. The authors have tried to overcome this by devising a standard severe infection in mice. The disease is produced by the intramuscular injection of 100 minimal doses of the bacteria with calcium chloride as a stimulant, followed an hour later in the same site by an injection of the chemotherapeutic drug under test. This interval of an hour does give consistent results with repeated tests. The most effective chemotherapeutic substances against the individual infections were penicillin against *Clostridium perfringens* and *Clostridium oedematiens*, and sulfathiazole against *Clostridium septicum*. The acridines possess a fairly powerful action against all three anaerobes though in a lower degree. Propamidine had a lower activity against all

three organisms, though its individual action in the case of *C. welchii* and *C. oedematiens* compared favorably with the sulfonamides. The tests show that no one drug is equally active against the three common anaerobes responsible for gas gangrene (*C. perfringens*, *C. septicum* and *C. oedematiens*). The best prophylactic results are achieved with the use of a mixture of drugs, and experience suggests the local application of a mixture of sulfathiazole and proflavine. The test the authors have used might be more aptly described as a prophylactic one. Owing to the rapidity with which gas gangrene spreads, the value of local treatment becomes restricted and general treatment, including antitoxins, is then essential.

Blast, Sudden Death and the Epiglottis—Observations on a man who died from an electric shock suggested to Eve that impaction of the epiglottis may be the explanation of sudden death from blast. The high pressure wave of blast, both in air and in water, compresses the thorax, expelling some air. The chest, being elastic, then expands, and air is drawn sharply inward. This rush of air might slam down the epiglottis and its effect would be reinforced by the low pressure wave, which sucks the walls of the thorax outward, just as it sucks glass out of windows. The epiglottis might thus be fixed firmly in position, as in the electrocution case, and there might not be enough air in the lungs to expire it upward again. If this is the mechanism in death from blast, survival will depend on such details as whether, at the time of impact, the person has just filled or just emptied his lungs, whether his mouth or nares are open, whether his ribs are rigid or flexible and whether his epiglottis is tilting downward as it does in swallowing. He has made a number of experiments with models representing the thorax and epiglottis, they clearly demonstrated a suction capable of slamming down the epiglottis. The hypothesis must eventually be proved or disproved by post mortem findings rather than by experiments. Positive evidence of impaction of the epiglottis should be diligently sought in blast victims by digital exploration or by postmortem examination. This evidence will not be found until it is specifically looked for. If the hypothesis is correct, death can be averted if the epiglottis is promptly replaced or if the vacuum holding it down is abolished by plunging a hollow needle into the trachea. Artificial respiration is futile till this is effected.

***Listeria Monocytogenes* in Infectious Mononucleosis**—Webb reports the clinical history of a student, aged 20, who presented the symptoms of glandular fever with swollen lymph nodes, pharyngitis, fever of three weeks' duration and a mononucleosis. The small quantity of serum available from the fourteenth day blood sample was used for the Paul and Bunnell sheep red cell heterophile agglutinin test. This gave positive agglutination to a titer of 1:2,048 (serum dilution). This result affords strong confirmatory evidence of glandular fever. The culture of the blood clot of the arm vein specimen taken on the fourteenth day of the disease yielded an organism the morphologic and cultural characteristics of which suggested *Listeria monocytogenes*. Its biochemical activities were therefore investigated and compared with those of three stock strains of this organism. The author describes the cultural and biological tests for this organism, including the appearance of the bacteria in experimental animals. He discusses the natural history of disease in animals caused by *Listeria* ("listeriosis"), and the relation of *Listeria* to certain types of human meningitis and meningoencephalitis and to infectious mononucleosis. The reported case furnishes the third instance of the association of *Listeria monocytogenes* and infectious mononucleosis. In the two previous instances the countries of origin were Denmark and the eastern United States of America.

Vitamin A and Dark Adaptation—Ludkin and his associates show that considerable differences of opinion have been expressed concerning the technique of measuring dark adaptation. Discussion has centered especially about the advisability of having a fixation spot or showing the test light in flashes and of using a form perception test rather than one of simple light perception. In their opinion many of the differences have been considered too much from the theoretical aspect; too few comparative tests have been done with different apparatus to determine whether and to what extent differences in technique produce different results. Various types of apparatus measure somewhat different functions. Thus the presence of a fixation spot will be of special value in determining the physiologic status of a fairly definite area of the retina; the absence of a fixation spot on the other hand allows the subject to find the most suitable parts of the retina with which to view the object and so to approach the practical conditions of vision at night. Using a modification of the Crookes dark adaptation apparatus, the authors have measured the course of dark adaptation in 400 apparently normal subjects. Repeated measurements showed that the readings for one subject are reproducible within narrow limits. In any one individual the variations rarely exceed 0.2 log unit for cone or rod threshold and two minutes for the cone-rod transition time. The course of adaptation varies considerably in different individuals and the visual threshold in the early stages of adaptation—especially in the first ten minutes—may bear no relation to the readings of the final rod threshold. This confirms the observations of other investigators but since many workers still use methods which give readings within a few minutes or even seconds of the onset of dark adaptation the importance of these observations is stressed. Administration of vitamin A as it affects dark adaptation at all always affects the final rod threshold. Other parts of the curve such as the cone threshold or the cone-rod transition time may not be affected. If single readings are to be used for assessing visual performance in the dark they are best made in conditions approaching complete adaptation.

Hippuric Acid Test in Thyrotoxicosis H. R. G. Poate, R. J. Bartholomew and T. E. Wilson—p. 481
Blackwater Fever: Review of Cases A. J. M. Nelson—p. 491

Hippuric Acid Test in Thyrotoxicosis—Poate and his associates discuss the results of 183 hippuric acid tests on 133 patients with diseases of the thyroid gland together with the results of 45 hippuric acid tests on 40 other patients. Basal metabolic rates and blood cholesterol, bilirubin and prothrombin levels were also estimated in many of these cases but it was not possible to prove a relationship between the results of any of these tests, the age and the sex of the patients, the duration of symptoms and the postoperative reaction. It is shown that in female patients suffering from thyrotoxicosis are grouped on a pathologic basis as (1) having acute thyrotoxicosis (hyperplastic thyroid gland) and (2) having toxic adenomatous thyroid. These two groups differ from each other in age, duration of symptoms and response to the hippuric acid test and in either series these factors of age, duration of symptoms and conjugation and detoxication are probably unrelated. It is therefore concluded that patients with toxic adenomatous thyroids show greater impairment of the conjugating and detoxicating function of the liver than do patients with acute thyrotoxicosis and that this difference is not entirely due to the longer duration of symptoms or to the increased age of the former group of patients. In the 9 fatal cases of thyrotoxicosis in this series the results of the hippuric acid test were not proportional to the changes in hepatic structure nor was there a relationship between the result of the hippuric acid test and the pathologic changes in the thyroid gland in those cases in which this gland was removed at operation or necropsy. It is concluded that impaired liver function is not the sole cause of thyroid crises and that from preoperative hippuric acid tests it is not possible to determine in which cases these crises will develop. The authors do not wish to convey the impression that the hippuric acid and other tests have usurped clinical judgment in the treatment of thyrotoxicosis; rather these tests are subservient to it. The hippuric acid test con-

firms the beneficial effect of preoperative treatment in cases of thyrotoxicosis and helps to establish the unsuitability of some patients for operation, especially many of those elderly patients with toxic adenomatous thyroids in whom the toxic state has existed for several years.

Some Remarks on Head Injuries J. E. Hughes—p. 509
Granulocytopenia Complicating Administration of Sulfonamides: Report of 2 Cases F. Catarinich and J. J. Hurley—p. 511

Rh Factor and Its Application to Obstetric Practice—Adam points out that antibodies (agglutinins) for the Rh factor do not normally occur in human plasma, so that when an Rh negative subject is given blood from an Rh positive donor as a first transfusion the reaction may be absent or slight, but Rh antibodies are nevertheless produced, so that a second transfusion from an Rh positive donor may be followed by a fatal reaction. In obstetric practice however, it is not necessary for a woman to be given a second transfusion before incompatibility reactions involving the Rh factor can occur. It was observed that most of the puerperal patients who had suffered transfusion reactions had been given blood from their husbands. Analysis of several of these cases demonstrated that the recipient was Rh negative and had moreover anti-Rh agglutinin in her serum and that the husband donor was Rh positive. The possibility was suggested that the antibodies have been formed in response to an antigen present in the fetus and inherited from the father but absent in the mother. The concept of isoimmunization by the Rh factor was thus developed and new light was thrown on the cause of erythroblastosis fetalis. If a blood transfusion is required for a woman during pregnancy or the puerperium it is best not to use the husband as the donor even though he is of the same blood group or a universal donor. It is apparently possible that some degree of isoimmunization may develop without producing signs of erythroblastosis in the infant but sufficient to produce anti-Rh agglutinins in the mother's serum. If a woman has given birth to an infant suffering from erythroblastosis fetalis and requires a blood transfusion in no circumstances must the husband be used as the donor, as he is almost certain to be Rh positive and the mother will be Rh negative; her serum will contain Rh antibodies and a severe or even fatal reaction will follow. The application of the available knowledge toward prevention of erythroblastosis fetalis lies in the premarital determination of the Rh character of the blood of the two persons concerned. It is doubtful however whether knowledge is yet sufficiently full to advise against marriage when the indications (as shown by the Rh factor) are unfavorable. It seems that the potency of the Rh antibodies developed through isoimmunization during the first pregnancy may not be sufficient to interfere with the birth of a healthy child on this occasion but that the risk of erythroblastosis or of icterus gravis neonatorum increases with successive pregnancies especially in the interval between them is short.

Schweizerische medizinische Wochenschrift, Basel

72 1369-1400 (Dec. 12) 1942 Partial Index

- Collaboration of Physician and Dentist in Dental Focal Infection W. Wiler—p. 1386

Pneumococcal Resistance to Sulfonamide Compounds—Grumbach and Hegglin examined 62 strains of pneumococci obtained from 36 cases for sensitivity to sulfonamide compounds. Clinical course and in vitro chemosensitivity corresponded in those cases which showed prompt clinical response as well as in those which showed poor clinical response and had a fatal outcome provided all other causes were excluded and the strains were immediately isolated from the sputum and tested. Decrease in virulence goes parallel with increase in resistance.

and increase in virulence with greater sensitivity to chemotherapy. Massive local administration of a sulfonamide compound increases the resistance to chemotherapy. Of strains which were repeatedly isolated in the course of a chemotherapeutically treated pneumonia, some showed unchanged sensitivity, others were more and still others were less sensitive on second isolation.

Elimination of Sulfathiazole in Breast Milk—According to Richen and Düry, at the women's clinic in Basel, Switzerland, about 55 per cent of the women are given sulfathiazole for a time after delivery. This raises the problem of the effect of the sulfathiazole on the nursing infant. The authors studied the elimination of sulfathiazole in the milk of 10 lactating women making 225 analyses. With a daily oral dose of 3 Gm, the elimination varied between 0.5 and 1.5 mg per hundred cubic centimeters, with a daily dose of 6 Gm, between 1 and 2 mg. The corresponding blood level was generally from two to three times as high as that of the milk. The largest amount of sulfathiazole ingested by a nursing infant in the course of a day was 4 mg. Between 0.3 and 2 per cent of the sulfathiazole ingested by the women appeared in the milk. This amount is too small to exert a therapeutic effect on the nursing infant. In comparative serial tests on 138 infants it was proved that with a maximal maternal dose of 6 Gm daily for five days the admixture of sulfathiazole to the breast milk exerted no influence on the infant. The weight curves of the nurslings whose mothers received sulfathiazole did not differ from those of the controls. Thus there is no reason to discontinue breast feeding when a mother requires the aforementioned doses of sulfathiazole.

Testosterone in Hypertension—The occasional coexistence of hypertension and impairment of sexual potency induced Marquez to inject testosterone propionate in the treatment of hypertension. At first he injected 5 mg once or twice each week. The effect being slight, he increased the dose to 10 mg, administered two or three times a week. Increasing the individual dose to 25 mg did not noticeably improve the results obtained with 10 mg. The favorable results sometimes became evident after from 50 to 80 mg had been injected, but he usually continued the treatment for from two to three months in order to retain the favorable results. He reviews the histories of 5 patients with hypertension in whom injections of testosterone propionate reduced the hypertension considerably and greatly improved the subjective symptoms and the general condition. At the time of his report the improvement had persisted for as long as nine months.

- *Vaccination Against Typhus and Vaccines Used H Hetch—p 341
- Facilitation, Shortening and Reduction of Risks of Delivery of Old Primiparas W Benthin—p 342

Vaccination Against Typhus and Vaccines Used—Hetch points out that passive immunization against typhus may be obtained with serum from convalescents or specifically immunized animals. The protection conferred is of short duration and the potency of the serums is not uniform. Vaccines prepared from rickettsias hold out best promise for active immunization. The author speaks of Weigl's work with rickettsias from the intestine of lice, Zinsser's studies in which the tunica vaginalis of rats was used and Cox's method of culturing rickettsias on the chorioallantois of incubated eggs. This last

vaccine has proved just as effective as Weigl's lice intestine vaccine. Vaccines have also been prepared from the hepatized lungs of experimentally infected mice, rabbits or dogs. A certain cross immunity exists between classic typhus and murine typhus, and repeated injections of vaccine from murine virus confer a certain degree of immunity, but the best protection is conferred by vaccines from homologous rickettsias. In regions in which murine typhus occurs mixed vaccines of *Rickettsia prowazekii* and *Rickettsia mooseri* can be used.

Sporadic Typhus—Luz reports observations on 41 cases of typhus in Leipzig, 36 of the patients were Poles and 5 were Germans. He stresses that the face of the patient with typhus is red and bloated, the eyelids are swollen, there are conjunctivitis and photophobia, the eyes are glassy, the speech is indistinct and oral pharyngeal symptoms are present. Fever rises rapidly and remains between 39 and 40 C (102.2 and 104.0 F) for from ten to fourteen days, fall in temperature is by lysis. The exanthem appears at the height of the fever, between the fourth and sixth days. It begins on the abdomen and shoulders and spreads rapidly over the entire trunk and the extremities. The face always remained free from the rash in the cases seen by the author. Splenic enlargement was present in all except the cases of mild disease. Involvement of the central nervous system was indicated by hallucinations, delirium, excitation and catatonic symptoms. Tremor and muscular contractions, defects in speech and hearing, and increased reflexes were observed. Typhus nodules in the brain were found at necropsy in 3 cases. Lumbar puncture in 6 cases disclosed increased pressure, the protein reaction was positive and the cell count was between 21 and 78. The arterial pressure was decreased. Except for mild anginal symptoms in a few patients, cardiac symptoms were negligible. Leukocytosis with counts from 10,000 to 13,000 existed at the height of the disease, there was an increase in neutrophils as well as eosinophils. There were some cases of extremely mild infection without exanthem. In these cases the Weil-Felix reaction was decisive for the diagnosis. The author stresses the great importance of this reaction. Among the Polish patients the mortality rate was 28 per cent, whereas among the German patients it was 40 per cent. This corroborates the observation that the disease is more severe in countries where it is not endemic.

- Experience with Use of Scopolamine Eukodal Ephedrine (High Dosage by Intramuscular Administration) in War and Peace H Engels—p 1
- Experiences with Peridural Anesthesia W Hueber—p 5
- *Action of Demerol in Surgery T Anda—p 8
- Fish Mouth Incision for Thigh Amputation in Gangrene K Schiele—p 11
- Observation on Local Tetanus L Rathcke—p 13

Demerol in Surgery—Anda reports observations on 150 persons to whom Demerol was given for the control of pain after ventriculography, brain operations and cerebral contusion, also before and after operations for gastric carcinoma, appendicitis, hernia and cholelithiasis, after operations for spinal tumor and for endarteritis obliterans. Demerol was administered in tablet form, by intramuscular injection and in suppository form. The author stresses that Demerol has primarily a spasmolytic effect, the analgesic action being less prominent. It was particularly effective in cases in which the cranial pressure was increased. It prevented vomiting in abdominal operations performed under local anesthesia. The analgesic effect of Demerol after major operations is less than that of morphine. Secondary effects and habituation were not observed.

Book Notices

Gout. By John H. Tallott, M.D., Associate in Medicine, Harvard University, Boston. Edited by Henry A. Christian, M.D., J.D., Clinical Professor of Medicine, Tufts College Medical School, Boston. [Reprinted from Oxford Texts of Medicine with the same page numbers as in that work.] Cloth, Price \$2.50. Pp. 79, 131 with 6 illustrations. New York, London & Toronto: Oxford University Press, 1944.

This small book is one of the best monographs on this poorly understood condition. It is a reprint from the Oxford Loose-Leaf Medicine. The book includes a comprehensive discussion of all phases of the disease and the results of the author's clinical and laboratory researches. Gout makes up about 5 per cent of patients who come to arthritis clinics. Clinical control in the acute stage can be accomplished by proper therapy. The author presents an accurate description of clinical gout and the researches on the metabolic phenomena of the gouty diathesis. The book contains many interesting and instructive illustrations. There is a brief historical section. The chemical, clinical, hereditary and metabolic aspects of the condition are well covered. The complications, associated diseases and differential diagnosis are described. The treatment is divided into that pertaining to prevention, the acute attack, the intercritical period and the chronic stage.

China's Health Problems. By Szeming Sze, General Secretary, Chinese Medical Association, Washington, D. C. Boards, Price \$1. Pp. 60. Washington, D. C.: Chinese Medical Association, 1943.

The author is editor of the *Chinese Medical Journal* and general secretary of the Chinese Medical Association. Since his visit to America in 1941 he has received requests for information about China's health problems and this small book contains that information. China has high morbidity and mortality rates, the former being 4 per cent of the population of 400,000,000 and the latter 25 per thousand of population. On any one day some 16,000,000 persons in China are ill and 10,000,000 persons die each year. Medical facilities with which to fight these high rates are meager. Only 12,000 doctors and 38,000 hospital beds are available whereas on the basis of moderate estimates of authorities there should be a minimum of 266,000 doctors and 2,000,000 hospital beds. Practically all of the modern facilities are in the large cities leaving the immense rural areas where 84 per cent of the people live virtually without any facilities. A determined effort by the government and by certain organizations and individuals is being made to improve the health of the Chinese and the foundations for a national health system have been laid. The author says, however, that since 84 per cent of the population are incapable of paying for private medical care it is agreed that the only solution is state medicine particularly in the rural areas. No attempt will be made to force state medicine on the cities where the public demands the services of private practitioners. The government's policy is to organize each of twenty-four provinces into districts each having several counties. A province will have one hundred district health centers each with some 30 hospital beds for emergency cases. A county will have sub-health centers which in turn would be served by health stations in each village. This plan forms a working basis. Although not ideal it has been only partly accomplished owing to limited funds and difficulties thrust on China in the last six years by Japan. To forward this plan there is the National Health Administration, a National Institute of Health which trains personnel and carries on research, the National Epidemic Prevention Bureau, the Central Narcotics Bureau, the Central Drug Factory and the Surgical Equipment Factory which provide drugs, supplies and equipment for the health services. Up to 1942 there had been established in areas not occupied by the Japanese seven hundred and eighty-three district health centers, sixteen provincial medical centers and fifteen provincial hospitals. In addition one hundred and fifty nongovernmental hospitals have linked their facilities with the National Health Services.

The greatest needs in the state medical system are hospitals and technical personnel. The author believes that the remaining one hundred and sixty nongovernmental hospitals in China should take their place as far as possible in a coordinated national system. These hospitals are willing and a beginning

has been made in some provinces. The boards of management of these additional hospitals, most of which are mission hospitals, are becoming more and more Chinese as the financial support obtained locally increases.

About 150,000,000 persons are estimated to have trachoma, 1,000,000 to have leprosy, 32,000,000 to have tuberculosis and 40,000,000 to have syphilis or gonorrhea, most of which diseases in health conscious countries are on the decline. The aim of the government is to educate the people in health matters. To aid in this movement the Health League of China, organized in 1940, is promoting health education in places not yet covered by the governmental health centers. China has twenty-eight medical colleges, ten national, nine provincial and nine private medical colleges. The biggest problem in medical education lies in the small schools of low standards which the Ministry of Education will have to subsidize to help them attract better teachers. Progress had been made up to the outbreak of war with Japan in 1937, but the war has seriously affected this program.

The Chinese Medical Association of some 3,000 members, which is practically the only medical scientific society cooperates closely with the government. The Medical Practitioners' Federation which is less efficiently organized, is composed largely of the poorly qualified doctors. In fact it is a federation of practitioners' unions which the law requires to open its membership to registered practitioners, irrespective of qualifications. The leaders of the Chinese Medical Association and the Medical Practitioners Federation recognize the need for closer cooperation but that will come only when the number of unqualified practitioners becomes a negligible part of the medical profession.

China is a land of famines which follow floods in the valleys of the Yellow and Yangtze rivers or droughts in the great plains of the northwest. China has its National Relief Commission and Red Cross but the latter should be reorganized. The United States since 1940 has sent lend-lease medical supplies and technical personnel to aid the Chinese army and the National Health Administration. Many other national Red Cross societies sent funds and supplies until the World War began in 1939 when gifts ceased with the exception of those from the American Red Cross. China's friends in many countries have organized United China Relief, the American Bureau for Medical Aid to China, the missionary bodies, the Associated Boards for Christian Colleges of China, China Child Welfare Inc. of New York and other cultural and relief bodies.

The author closes his book with a brief chapter on medical supplies listing those which are particularly scarce and the raw materials for the manufacture of medical supplies which are sufficient.

Emotion in Man and Animal: Its Nature and Relation to Attitude and Motive. By Paul Thomas Young. Cloth, Price \$4. Pp. 42, with 28 illustrations. New York: John Wiley & Sons Inc. London: Chapman & Hall Limited, 1943.

This is another of those run of the mill textbooks whose author professes to offer an authoritative discussion relative to problems of human behavior. As such it is probably no worse and certainly no better than most such works which are now utilized to teach psychology in many of our presumed institutions of higher learning. This is only another way of stating that most such volumes are completely outdated and many of their concepts long discarded or in some instances, the discussions although supported by modern theories and experimental research are entirely inadequate in attempts at presentation of dynamic emotional concepts. It is discouraging to read a book which as the author states in the preface has not only been arranged in form convenient for classroom use but which he has obviously intended for popular consumption to find that the contributions of leading past and present research workers in the field of human and animal emotions have been either vaguely mentioned or entirely ignored. The anthropologic, experimental and research contributions of such men as Frazer, Mantegazza, Mahinowski, Roheim, Freud, Carl Abraham, Magnus Hirschfeld, Franz Alexander and his co-workers, Kurt Lewin and his group, Carl Menninger and his associates, H. W. Gant and Jules Masserman only to mention a few are either ignored or are referred to quite casually and superficially. Freud's monumental contributions to the understanding of

ing of human emotions receive only passing attention in the text and are left out of the recommendations for reading as well as the author's index. It seems unfortunate to this reviewer that modern dynamic psychology as understood and taught by prominent men and women in the field has not been introduced to more of our larger universities.

A Manual of Otolaryngology, Rhinology and Laryngology. By Howard Charles Ballenger, M.D., F.A.C.S., Associate Professor of Otolaryngology, Northwestern University School of Medicine, Chicago. Second edition. Cloth. Price \$1. Pp. 374 with 117 illustrations. Philadelphia: Lea & Febiger, 1941.

Obviously no author could write a manual on diseases of the ear, nose and throat that would satisfy every laryngologist who is engaged in teaching undergraduates. The material that must be compressed within the narrow confines of a small book is too vast to permit adequate condensation without slighting certain topics which to some teachers are more important than those selected by this author. If the purpose of such a book is to present in as concise a manner as possible the essential and important features of the specialty and to emphasize vital diagnostic signs, Ballenger's book comes as close to filling the bill as is humanly possible. In the new edition the text includes the latest data. Sufficient emphasis is still placed on the important and serious complications which may often perplex the general practitioner, as indeed they frequently do the specialist. The chapters on neck infections, foreign bodies in the air passages, intracranial complications, and Meniere's disease are worthy of special mention. The student or general practitioner who uses a book such as Ballenger's should always bear in mind that the author is presenting only the bare essentials which are offered as foundation stones on which the reader is to build as he progresses in the practice of medicine and his experience widens. Because of the limitations of space the text must be condensed and it is therefore important that it be read carefully, since every sentence means something. One might add only the tiny regret that the author had so little to say on the subject of the sulfonamides in otolaryngology, a topic on which much has recently been written.

Bacteriology for Students of Medicine and Public Health. By Pinar Telford, Ph.D., Professor of Bacteriology, University of South Dakota School of Medical Sciences, Vermillion. Medical Students Series, edited by Fred C. Zapffe, Secretary, Association of American Medical Colleges, Chicago. Cloth. Price \$5. Pp. 526 with 153 illustrations. New York & London: Paul B. Hoeber, Inc., 1942.

The first half of this book is devoted to the general aspects of bacteriology as found in most textbooks. The author then takes up epidemiology and biostatistics together with the major communicable diseases, because he "feels that it is just as important, if not more so, for the medical student to understand bacteriology as it is for him to know it." The author indulges in considerable freedom, such as placing the tularemia organism with the *Brucella* group and the cause of rat bite fever with *Actinomyces*. The terms "undulant fever" and "brucellosis" are used interchangeably in different parts of the book. Some of the charts showing incidence of disease by years unfortunately lack figures for the last decade. In one instance a commercial preparation is specified by name for use as a disinfectant. These isolated instances do not detract from the book as a whole, however, and are offset by many excellent features.

Discovering Ourselves: A View of the Human Mind and How It Works. By Edward A. Strecker, A.M., M.D., and Kenneth E. Appel, Ph.D., M.D., in collaboration with John W. Appel, M.D. Second edition. Cloth. Price \$3. Pp. 434 with 28 illustrations. New York: Macmillan Company, 1943.

The first edition of this work was published more than twelve years ago. The book explains in nontechnical language the essentials of modern psychology and the principles of psychiatry and mental hygiene. The usefulness of the previous edition prompted the development of the present volume, which includes new chapters on emotion, fear and anger and incorporation of the ideas of psychosomatic medicine. There is also attention to special problems created by the war. Another addition to the work is an appendix providing a series of questions on the individual chapters. The book is well printed, easily readable, and can be recommended to physicians as a work which they, in turn, can confer on patients who need therapeutic literature.

Trail to Light: A Biography of Joseph Goldberger. By Robert P. Parsons. Cloth. Price \$3. Pp. 373 with portrait. Indianapolis & New York: Bobbs-Merrill Company, 1943.

The story of the accomplishments of Dr. Joseph Goldberger should by this time be well known to most members of the medical profession. His life was devoted largely to study of infectious diseases made under the auspices of the United States Public Health Service, but the climax of his career came with his basic contributions to our knowledge of pellagra. The book is based largely on letters which Dr. Goldberger wrote to his wife over some twenty-three years and on collections of news paper clippings and other memorandums which had been assembled in a chest which was made available to the biographer. Dr. Goldberger's career might well serve as an inspiration to young men who contemplate work with the United States Public Health Service as a career.

Fractures and Fracture Treatment in Practice. By Kurt Colsen, M.D., Tutor to the Department of Surgery, Registrar to the Surgical Firm of the University of the Witwatersrand, Johannesburg. Fbrikold. Price 12s. 6d. Pp. 117 with 157 illustrations. Johannesburg: Witwatersrand University Press, 1942.

This handy book was written by a man who has conducted the fracture tutorial course in connection with the class of systematic surgery in the Witwatersrand University at Johannesburg, South Africa. It serves its purpose well. The manuscript is brief and to the point. The illustrations are line drawings and are simple and instructive. The book reflects the teachings of Böhler and Watson Jones. It is an excellent book for medical students and general practitioners.

Whooping Cough. By Joseph H. Lipin, B.Chem., M.D., Adjunct Pediatrician, Bronx Hospital, New York. Cloth. Price \$4.50. Pp. 278 with illustrations. Springfield, Illinois & Baltimore: Charles C. Thomas, 1943.

This monograph is written in an easy, understandable style. It contains abstracts of all the worthwhile literature on whooping cough. It covers epidemiology, immunology, bacteriology and the preparation of various endotoxins and exotoxins. It also describes the clinical manifestations of the disease. The author has attempted to make a critical analysis of the literature and gives his own interpretations and evaluations of the various studies. In this he has succeeded very well. The illustrations are excellent. It is an invaluable book for the investigator and is equally valuable and practicable for the practitioner.

Central Autonomic Regulations in Health and Disease with Special Reference to the Hypothalamus. By Heymen R. Miller, M.D., Associate Attending Physician, Montefiore Hospital, New York City. Introduction by John F. Fulton, M.D., M.A., D.Phil., Sterling Professor of Physiology, Yale University, New Haven. Cloth. Price \$5.50. Pp. 430 with 61 illustrations. New York: Grune & Stratton, 1942.

In the coordination of actions of the human body the cerebral cortex and the hypothalamus play most important parts. This book offers a concentration of the general physiology of the autonomic nervous system and special considerations of the manner in which the temperature of the body, the use of water and minerals, metabolism, circulation, respiration, sleep, the emotions and other functions are controlled. The arrangement of the book is such that the fundamental anatomy forms the subject of the concluding chapters. As is pointed out by Dr. John F. Fulton in his preface, the physiology of the autonomic nervous system has tremendous application to clinical practice. The author has considered the available literature, most of which is reviewed in this book. The case reports in many instances indicate the technic of application of the knowledge concerned to the care of the sick.

Mercy in Hell: An American Ambulance Driver with the Eighth Army. By Andrew Geer, Captain, American Field Service. Cloth. Price \$2. Pp. 264 with illustrations. New York & London: Whitlitsky House, McGraw-Hill Book Company, Inc., 1943.

This is a record of the work of an ambulance driver who was with the Eighth Army in the battle in North Africa up to the time of the Tunisia campaign. It is a graphic record of the part played by the Medical Corps in a situation in which it worked under tremendous difficulties. Unfortunately the author lacks the literary ability necessary to dramatize the terrifically dramatic events in which it played a central part.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INTERMITTENT HYDRARTHROSIS

To the Editor—A woman aged 35 has been married five years and has never been pregnant. The patient's chief complaint is that during the past four or five years both knees have become swollen to such an extent that they cannot be bent. This swelling comes every ten days and lasts for three or four days. After five days the swelling disappears gradually so that she can bend her knees again. For about one week there is no swelling at all but at the end of the week the swelling returns. There is no relationship in time to her menstruation or to the weather. The swelling is the same in the morning as it is in the evening. There is dull pain in the knees at the time they are swollen but there is neither redness nor fever. The swelling consists of a pronounced edema above and below the knee joint. Menstruation is regular and without pain. Examination of the abdomen and pelvis does not reveal anything abnormal. Venules are prominent in the thighs above her knees. The history and findings are otherwise negative except that she is nervous and comes of a nervous family. I have seen the patient when the knees were swollen and the swellings were prominent.

M D New York

ANSWER—This patient appears to have intermittent hydrarthrosis. During approximately a hundred years since the disease was recognized the incidence of reported cases has been only about 1 each year. Many cases, however, are not reported.

Two varieties of the disease are encountered. The first type has been designated symptomatic intermittent hydrarthrosis because the recurring articular swellings prove to be early symptoms of a progressive rheumatoid type of arthritis which later appears in the joints involved by the periodic edema or in other joints. In this form the cycles are often regular for varying periods, sometimes for many months. Later the periods of freedom between swellings become shorter and the degree of recovery from attacks is less complete. A second form of the disease has been called idiopathic intermittent hydrarthrosis because some observers believe that neither rheumatoid arthritis nor any other cause has been demonstrated. Most persons with either form eventually acquire rheumatoid arthritis. Furthermore, synovial membranes from both clinical types of the disease removed in attempts at surgical cure have shown identical pathologic changes, namely, synovial edema and villus formation, scattered and follicle-like infiltration of sub-synovial tissues with lymphocytes and endothelial cells, regions of hyaline degeneration of fibrous tissue, thickening of the endothelial layer by enlargement of endothelial cells, and reduplication of the lining endothelium. Thus remissions in both forms are only apparent. The underlying synovitis is permanent and progressive.

The syndrome of intermittent hydrarthrosis affects men and women with equal frequency. The remitting swellings always appear in the knee although occasionally another joint such as the ankle, hip and rarely a joint of the upper extremity may also be involved. The intervals of freedom vary in length from two or three days to three weeks, being in most instances from seven to ten days. The swellings generally last three to five days. Attacks cause discomfort in the form of swelling, tightness and stiffness from distention of the joint by exudate. Pain is generally moderate but may be severe and may require rest in bed or immobilization of the affected joint. The attacks are not associated with fever and despite the acuteness of the swelling there is no redness, pronounced heat or notable tenderness and there are no striking signs of constitutional reaction during the attacks. When the swelling has cleared the joint may appear to be completely recovered. In some instances periods of complete freedom from attacks may intervene. Such periods may be of months or years' duration only to be followed by recurrence of regular cycles.

Laboratory data are variable. Some patients (in whom the condition is of the so called symptomatic form) have secondary anemia and elevation of the sedimentation rate.

The cause is unknown. Its periodicity suggested to many investigators that the condition might represent an allergic reaction either to bacteria or to some other irritant agent. However, such evidence as has been adduced to support the allergic hypothesis is purely inferential.

During the acute attacks patients are more comfortable at rest. Some comfort may result from supporting the knee with an elastic bandage. Physical therapy and acetylsalicylic acid

generally provide some relief during the attacks. Measures worthy of trial in an attempt to prevent recurrences of the attacks include intravenous administration of typhoid vaccine and removal of infected teeth if any can be demonstrated. Synovectomy has been recommended by some physicians, but others have found that progressive arthritis appears (sometimes in other joints) despite synovectomy. The disease is said to have been stopped after administration of ergotamine tartrate in doses of 1 mg daily for approximately two months followed by repeated courses of one tablet daily for periods of about a month when attacks tend to recur. Attacks are said to have stopped in 1 patient when foods to which the patient was sensitive were eliminated from the diet. De-sensitization with histamine by means of intravenous and intramuscular injections of this substance has failed to influence the course of the disease in several instances.

The prognosis must be considered decidedly uncertain. In many instances the regular recurrence of attacks has continued for years even for two or more decades without any change in the nature of the symptoms. In most instances, however, the patient eventually acquires definite rheumatoid arthritis.

DICHLOROACETIC VERSUS TRICHLOROACETIC ACID FOR WARTS

To the Editor—I am interested in the use of bichloroacetic acid as a corrosive agent in the treatment of warts although I have seen no literature on the subject. However, this compound is inordinately expensive. Is there any great superiority in the use of this compound as compared with trichloroacetic acid? If so are there any approved relatively inexpensive products with this active ingredient which could be used for this purpose?

Colonel M C U S Army

ANSWER—It is true that dichloroacetic acid marketed by the Kahlenberg Laboratories under the name bichloroacetic acid is somewhat more expensive than the better known trichloroacetic acid which is an official drug listed in the U S Pharmacopeia XII. Chemical supply houses currently list a reagent grade of dichloroacetic acid at a cost of \$4.54 per pound while trichloroacetic acid U S P costs only \$3.45 per pound. The current retail price of bichloroacetic acid in the 1/2 ounce size with kit for application is \$2.50. In contrast it is possible for a pharmacy to purchase dichloroacetic acid from a photographic supply house bottle it in 1 ounce bottles (the bottle costing approximately 25 cents) and sell it for \$1.

When used in concentrated form for caustic action the two give much the same result. The stinging due to the trichloroacetic acid is slightly greater, but both cease to sting in a few minutes. The area treated becomes white and loses sensation while about it the skin becomes pink and slightly swollen. In a short time the swelling and flush subside and a grayish white area is left about which a narrow zone of deep red is seen which persists. So far as could be seen by a trial on the writer's forearm the action of the two drugs in concentrated form the bichloroacetic acid sold by Kahlenberg and a saturated solution of trichloroacetic acid made by adding a few drops of water to some crystals of trichloroacetic acid was equal causing a superficial necrosis of the same degree in the two.

THERAPEUTIC FASTING FOR HYPERTENSION

To the Editor—I am interested in the therapeutics of fasting. Is there any authoritative literature on this subject especially as to its effect on degenerative diseases and hypertension? Can you discuss it briefly?

M D Canal Zone

ANSWER—The effect of fasting and of modified fasting (consuming only fruit and vegetable juices) in hypertension was studied by Kampmann in Volhard's Clinic (Frankfurt on Main). Kampmann and Volhard recommend the use of fasting as a means of reducing high blood pressure. However, Volhard points out that a high blood pressure should be regarded only as a symptom like fever and the specific cause should therefore be sought and treated. Nevertheless, the reduction of a high blood pressure by fasting, modified fasting or fluid and salt restriction may alone suffice to bring about considerable general improvement in some cases. Recently Laird reported a 20 per cent reduction in blood pressure as one of the incidental benefits derived by internees in a Japanese internment camp where the food supplies were quantitatively inadequate.

The reduction in some cases of high blood pressure by fasting or food restriction is attributed to a reduction of the ordinary metabolic strains on the circulatory system and the kidneys. Fasting is also regarded by some as beneficial in other conditions because it is believed that it gives the eliminative organs a chance to reduce accumulated toxic products, facilitates more complete oxidation in the body, uses up or

OBSCURE RECURRENT LESIONS OF MOUTH

To the Editor—A well built lean professional man aged 38 has had periodic attacks of stomatitis for eleven years worse in the last nine. The lesions begin as red areas of various shapes and sizes which ulcerate in a few days leaving a gray or red base. At this stage bad breath develops some regional adenitis fever up to 103 F and 11 000 white blood cells. Lesions are located in the lower fornix of the mouth between the cheeks and the jaws the upper fornix the floor of the mouth beneath the tongue the uvula the pharynx and the upper surface of the tongue in that order of severity and frequency. The gingiva itself is not involved except in one place where a first lower molar is missing. There the upper surface of the gingiva was once involved. The alveolar bone and gingivae are otherwise normal. Each attack has a gradual onset and after reaching a peak resolves rapidly. The attacks last four to seven weeks usually six weeks the peaks of the attacks are about two to four months apart usually three months and the period between attacks when he is entirely well is one to six weeks usually four weeks. During several attacks there has been slight burning on urination and a 2 mm zone of redness of the glans about the meatus. The only other significant fact is that with rare exceptions he has not had a bowel movement without an enema for nine years. He gets a headache and feels sluggish every three days and takes an enema of 1 quart of lukewarm tap water. The stools are hard and normal in color. The barium enema revealed some hypermotility of the descending colon. Gastric analysis urine and blood studies including Wassermann and Kahn tests were normal. Cultures of the lesions were reported to show thrush and other organisms and a slight indication of Vincent's. Treatments tried include large doses of hydrochloric acid neosarsphenamine intravenously various local oxidizing agents daily injections of 100 mg of niacin with 33 mg of thiamine and 1 Gm of sulfathiazole every four hours. Malaise followed five doses of sulfathiazole but he was close to relapse anyway. None of these treatments were consistently followed by improvement. No correlation with seasons is apparent but there is some correlation with periods of mental stress. Suggestions would be appreciated.

M D California

ANSWER—The recurrent oral lesions have apparently been well studied. They do not suggest a local cause although more complete bacteriologic data might be useful. The failure of arsenicals vitamin B concentrates and one of the sulfonamides is helpful in a negative way.

The lesions might have a neurogenic basis with the local infection being secondary and atypical. The occurrence during periods of stress and in association with a spastic colon is suggestive.

There would be several trial approaches possible.

1 Treat the general and intestinal tension by use of sedatives (phenobarbital $\frac{1}{4}$ to $\frac{1}{2}$ grain [0.016 to 0.032 Gm] three times daily) plus a drug aimed at autonomic nerve depression. Combine this with a bland diet.

2 Prepare a vaccine from the stools for desensitization (as suggested for various lesions by MacIntosh and Hill).

3 Try succinylsulfathiazole in an attempt to change the intestinal flora. This drug is almost nontoxic is scarcely absorbed into the blood and often softens the stool. The initial dose is 0.25 Gm per kilogram of body weight, followed by 0.25 Gm per kilogram daily divided into four or more doses.

INHERITANCE OF PSEUDOHYPERTROPHIC MUSCULAR DYSTROPHY

To the Editor—A primipara aged 36 now five months pregnant has had progressive muscular dystrophy of a pseudohypertrophic type with involvement of the back and thigh muscles for approximately three and a half years. She had some sort of infection called meningitis at the age of 2½ years and she was unable to walk well until she was 5 or 6 years of age. With the resumption of walking she developed normally and was able to go through high school and a teaching career engaging in horseback riding basketball tennis and the other common sports without noting any weakness. The trouble has been gradually making its appearance during the last three and a half years and since the beginning of pregnancy the symptoms have been aggravated. Can the patient be carried safely through several more months of pregnancy and then an elective cesarean section done with sterilization? What is the prognosis with regard to the baby? Do you advise interruption of the pregnancy at once with sterilization? One brother died at the age of 19 with so called Bright's disease but he had a weak back. One sister died at the age of 30 with pneumonia but she had had a weak back for five years preceding the pneumonia on account of typhoid.

M D South Carolina

ANSWER—It is doubtful that the infection at the age of 2½ years called meningitis has any direct relation with the patient's present condition. Although somewhat late in onset it is probable that the patient is suffering from pseudohypertrophic muscular dystrophy although such a diagnosis cannot be made without equivocation as there was a long history of good health and normal muscular action up to the third decade of life. It is not unusual however for the condition to be aggravated during pregnancy. Lacking here is an exact description of the patient's present condition moreover the evidence that her brother and sister both deceased had weak backs does not definitely confirm the diagnosis of the familial type of pseudohypertrophic muscular dystrophy.

If the diagnosis is correct, and particularly if the condition has appeared in previous generations of the family, one has seriously to consider the possibility of transmitting this disease to another generation. Whether this would take place in an individual case is not an easy question to decide. The disease is inherited in about 50 per cent of the children the sexes being approximately equally affected. This is based on studies of cases in which the disease appeared in successive generations and had the characteristics of a mendelian domination. On the other hand, if the disease has not occurred in previous generations it may be looked on as a recessive factor and the chances of inheritance are much less. There are sporadic cases, usually occurring in the male, and these appear in a frequency of about three to one. It is impossible therefore, to give any prognosis with regard to the baby in the case presented. There is no indication as far as the mother is concerned that the pregnancy should be interrupted on account of her disease. Advice with regard to the continuance of the pregnancy based on the possibility of inheritance cannot naturally be given to the patient in a categorical manner. All one can do is to place the known facts before the patient. In the case presented here there are so many unknown or at least uncertain, factors that definite advice cannot justifiably be given.

SERUM ALBUMIN AND TOXEMIA OF PREGNANCY

To the Editor—I am on duty in the Southern Pacific area and naturally find it impossible to try the efficacy of the following idea. While reading a belated article and editorial on the use of human serum albumin in counteracting the plasmapheresis of shock it occurred to me that similar treatment might hasten the alleviation of the preeclamptic state. Of course plasmapheresis does not manifest itself in preeclampsia for we are dealing with albuminuria primarily as far as the loss of albumin is concerned. I should appreciate knowing whether or not such experimental treatments have as yet been attempted in obstetric clinics. If not what do you think of my idea and the possibility of administering human serum albumin in an effort to raise the osmotic pressure in the blood with the possible resultant relief of the concomitant rise in blood pressure and the excessive gain in weight?

Captain M C A U S

ANSWER—There have been no reports in the literature on the administration of human albumin to patients with preeclampsia and eclampsia. Serum albumin concentration is usually depressed in toxemia of pregnancy and although this depression tends to enhance edema formation the basic cause for fluid retention is considered to be primarily renal or possibly endocrine in origin. Its correction is therefore of secondary concern only in the management of the fluid retention and of the hypertension.

Blood volume is increased in pregnancy and there is a distinct tendency to pulmonary edema in preeclampsia and eclampsia. Human serum albumin is supplied as a 25 per cent solution which has about five times the osmotic attraction of plasma. Its administration would increase further the plasma volume with the resultant danger of precipitating an acute pulmonary edema. The administration of plasma or of whole blood has been advocated for the control of the peripheral circulatory failure (shock) to which these patients frequently succumb but these must be administered slowly over the course of several hours in order to prevent pulmonary congestion.

LECITHIN AND ITS USE IN FOODS

To the Editor—One hears now a good deal about lecithin as an ingredient of artificially prepared foods. Please tell me what is meant by lecithin in such cases. What are its sources and how is such lecithin prepared?

M D Maryland

ANSWER—Lecithins are the phosphatides or esters of fatty acids and glycerophosphoric acids which contain choline. They are compound molecules consisting of one molecule of glycerol two molecules of fatty acids or molecule of phosphoric acid and one molecule of choline linked together by loss of an H or OH ion. Formerly lecithin was prepared from egg yolk. Lecithins are present in many plants and especially in cereals.

and legumes. Most commercial lecithin is now prepared from soy beans and is often sold as a lecithin hydrate, which has the advantage of being water soluble. It is usually obtained by a modified alcohol extraction (see Horvath, *A. A. J. Chem. Education* 14:424, 1937 for details). Because of its emulsifying properties lecithin has many food uses. Recently one of its constituents, choline, has assumed increased dietary importance because it has been found similar to vitamins in physiologic significance. Lecithin is used in candy, margarine, shortening, food fats and oils, biscuits, crackers and other food commodities. It is added to cocoa butter used in chocolate in amounts up to 0.4 per cent.

Lecithin hydrate is manufactured by Jungmann & Co., Inc., New York, from whom details as to its use in food products can possibly be obtained.

FLUORESCENT LAMP NOT RESPONSIBLE FOR ASTHMA IN WATCHMAKER

To the Editor—A man aged 50, a watchmaker for the past thirty years with a history of prolonged jaundice of unknown etiology at the age of 12, complains of fatigue, sneezing, nasal discharge and some bronchial congestion. These symptoms are of recent date and he associates them from the time he has been working under a fluorescent lamp (mercury?). He claims that when the lamp is removed the symptoms gradually disappear in several weeks and manifest themselves again when he resumes his work under the fluorescent lamp. He is well developed for a man of his age and routinely takes calisthenics, hikes and swims. At his work he uses naphtha, carbon tetrachloride and alcohol at various intervals for cleansing purposes making sure of good ventilation. He gives no history of any past asthmatic or allergic manifestations. He refuses any studies because he has been symptom free since avoiding the use of the lamp. Are there any reports as to fluorescent rays causing these symptoms? Can the chemicals which he has used for a period of years without any difficulty now be responsible for these symptoms?

M. D., Pennsylvania

ANSWER—The sneezing, nasal discharge and bronchial congestion are almost certainly not due to the fluorescent lamp. They may, however, be caused by naphtha or carbon tetrachloride and perhaps by alcohol, as inhalation of these vapors is not infrequently responsible for similar symptoms. Chemicals may begin to cause symptoms after a prolonged period of exposure.

A letter of inquiry to the Lighting Research Laboratory of the General Electric Company confirms the statement that exposure to the fluorescent lamps cannot cause these symptoms. Matthew Luckiesh, the director of this department, writes as follows:

The radiant energy emitted by the fluorescent lamp is entirely within the spectral range of natural sunlight or natural skylight. The fact that it is a low pressure mercury arc is of no consequence as far as the radiant energy is concerned. The phosphors with which the inner surface of the glass tube is coated transform the short wave ultraviolet energy into visible energy or light. These are opaque to ultraviolet energy not found in sunlight and in addition we design the spectral transmission of the glass so that no measurable amount of energy shorter than the short wave end of the spectrum is transmitted.

So much for the light from the fluorescent lamp. Of course, the light can be misused, that is, the lighting may be bad. There may be glare direct from the light source or specularly reflected from the work. However, I know of no reason why glare should produce the results complained of. I am certain that the effects which the patient experiences have nothing to do with the light from the fluorescent lamp. He should experience the same effects outdoors in the sunlight if light is the cause. I have traced down a variety of complaints and none of them are traceable to the light and radiant energy from the fluorescent lamp."

OCCCLUSION OF RETINAL ARTERY IN PREGNANCY

To the Editor—A patient had an occlusion of the central retinal artery of the left eye which resulted in almost total blindness of that eye. This occlusion occurred when the patient was three to four months pregnant. Except for the eye, the physical examination is negative. Should the patient have more children? Would occlusion be likely to occur in the other eye if she should again become pregnant? What was the relation, if any, between the retinal vessel occlusion and the pregnancy?

Henry W. Ten Pas, M.D., Holland, Mich.

ANSWER—It is exceedingly unusual to have thrombosis of the central artery occur during uncomplicated pregnancy. If there was an acute rise of blood pressure during the pregnancy, such an event may have been due to or precipitated by arterial spasm. If there was no rise of blood pressure, however, there would be some doubt whether the closure of the central artery had any relation to the pregnancy. In view of this doubt it would probably not be necessary to prevent further pregnancies, since the likelihood of such an event occurring during the subsequent pregnancy would be exceedingly slight.

CALCIUM DEFICIENT DIET AS AID IN CORRECTING BONE DEFORMITIES

To the Editor—Can you discuss the reduction of deformity of the long bones by a diet poor in calcium and rich in phosphorus and the application of casts to the straightened bone as soon as the absorption of calcium has been sufficient? J. W. Hopkins, M.D., Glendale, Calif.

ANSWER—In an article published in the *Archives of Surgery* (28:742 [April] 1934) Ghormley and Stuck described an experiment in which Ghormley had been assisted by Aub and Bauer of Boston. This consisted in the feeding of a low calcium diet with the development of a definite negative calcium balance for a patient in whom correction was being attempted for a severe scoliosis. It was the opinion of the authors that this aided in obtaining correction and that the bones at the time of operation were found to be much softer than normal. Furthermore, it was their opinion that calcification and new bone formed more rapidly in this patient after operation when the patient was again placed on an adequate diet than had been seen in patients who had not gone through an initial period of decalcifying of bone through diet. Several other surgeons have attempted to make bones sufficiently soft to be able to reshape them by feeding a diet poor in calcium and rich in phosphorus or through the administration of ammonium chloride.

As an addition to this program, Nachlas of Baltimore found that, if a plaster cast was applied to the extremity in which there was a deformity which the surgeon wished subsequently to correct while the patient was being given a diet insufficient in calcium, the bones in that extremity atrophied more rapidly than did those of the rest of the body because of the immobilization. Nachlas expressed the opinion that in certain cases it was possible to correct these deformities, which otherwise probably would not have been correctable without open surgery. This work was not published but was discussed before several groups of physicians.

The methods referred to, however, have not been accepted as practicable by a vast majority of orthopedic surgeons. As far as the literature would indicate, and from discussion with orthopedic surgeons, it seems probable that the method will never be used widely.

MICROSEDIMENTATION TESTS OF BLOOD

To the Editor—How do the Landau-Adams microsedimentation apparatus and the Brandenburg microsedimentation apparatus compare in accuracy with the macromethods such as the Westergren and the Wintrobe-Landsberg? I shall appreciate any information on this subject that you can give me.

Wesley R. Heard, M.D., Pasadena, Calif.

ANSWER—The Landau-Adams and the Brandenburg microsedimentation tests represent the modification of the Linzenmeier-Raunert method described by Landau (*Am. J. Dis. Child* 45:691 [April] 1933). Landau's extensive studies with the method demonstrated its reliability and its simplicity, particularly after the introduction of the check syringe as a means of mechanical aspiration. The chief criticism of this method is that the column of citrated blood sediments within a capillary pipet whose inside bore is 1 mm. In this respect this method shares the inadequacy of other types of sedimentation apparatus in which a capillary pipet is employed. Wintrobe and Landsberg (*Am. J. M. Sc.* 189:102 [Jan.] 1935) and Ham (*Medicine* 17:447 [Dec.] 1938) have pointed out that the settling of the red cells in tubes with an internal diameter of 2 mm or less may be slow and uneven. Since the Westergren and the Wintrobe-Landsberg macromethods employ tubes with internal diameters of 25 mm, greater accuracy is assured. The ideal micro method, from the standpoint of accuracy, is one which utilizes capillary blood but which employs a sedimentation tube with the basic specifications of a standard venipuncture method. Such methods have been described by Cutler (*Am. J. M. Sc.* 173:687 [May] 1927) and by Smith (*ibid.* 192:73 [July] 1936).

PREPUTIAL ULCER FROM AMMONIACAL DERMATITIS

To the Editor—I have just come on the note on "Stenosed Urethral Meatus in Young Boy" (*The Journal*, June 5, 1943, p. 409). To me the crusting about the glans penis and terminal urethra sounds much like a preputial ulcer from an ammoniacal dermatitis. It would be important to know if the child still has enuresis and if there is a strong ammonia odor about the child on awakening. If this is so all one has to do is rinse the clothing in a final rinse of 1:5,000 mercury bichloride after washing and this will have a bacteriostatic effect on the urethra-splitting organisms, which form ammonia (NH₃) from the urea in urine. This, of course, is a common finding in pediatrics and responds beautifully to this method of therapy. Locally nothing really needs to be done, because as soon as ammonia ceases to be formed the ulcer heals.

INTENSIVE METHODS OF TREATING SYPHILIS

H. N. COLE, M.D.
E. B. HEISEL, M.D.
AND
GEORGE STROUD III, M.D.
CLEVELAND

Paul Ehrlich worked for years synthesizing an arsenical compound to cure syphilis. The *therapia magna sterilisans*, he thought had been achieved with his six hundred and sixth preparation, arsphenamine (introduced as salvarsan), to be injected intramuscularly, one injection sufficing. Relapses as well as reactions disclosed differently and he synthesized another arsenical neoarsphenamine, and later still others. When none of these worked he and his collaborators suggested use of more than one injection. Every physician agreed to the effect of the trivalent arsenical salts on *Treponema pallidum*, but it required trial and error as well as evaluation of enormous amounts of case material before medicine finally awakened to the profound effect of these compounds on syphilis. Injections of the arsenical were at first widely spaced between other forms of therapy—mercury. Later a physician here and there had the temerity to use injections perhaps once a month later once a week. It was one of our American dermatologists, Sigmund Pollitzer, who suggested three daily injections of an arsenical followed by a course of mercury, then a rest and repetition of the foregoing. Unfortunately, the worthwhile part of Pollitzer's advice was ignored since his cases relapsed far more frequently than other cases treated in a continuous fashion, the relapse being due to the rest period as we now see it. However, Pollitzer's idea was not forgotten. Quite early the Cooperative Group studies showed that it was not only type of therapy but also amount of therapy given in a continuous manner that played so great a role in "cure." Probably the crystallization of all these studies was the statistical survey of Padgett's¹ indicating the importance in acute syphilis of the number of arsenical injections and conversely the time span in which they were given after inception of the disease.

INTRAVENOUS DRIP THERAPY OF SYPHILIS

A further great stride in syphilotherapy was worked out by Chargin, Hyman, Leifer and their collaborators.² They found that when active or inert chemicals, drugs and biologic products are injected intravenously in a rapid manner they may give rise to alarming symptoms so-called speed shock. On the other hand, by regulating the rate of flow of the preparation by means of an intravenous drip so that not more than 2 to 3 cc a minute was injected, they were able to introduce even toxic substances like histamine without difficulty. Experiments were then tried on man with like results and Chargin felt that the method might be applied to the use of larger doses of the arsenicals than are ordinarily employed in treating syphilis. First observations were made with neoarsphenamine and results were very promising, but reactions, especially peripheral neuritis and cerebral symptoms, were high and after some ineffectual attempts to use arsphenamine they turned to mapharsen. The dose employed was 240 mg daily dissolved in 2,000 to 2,400 cc of 5 per cent dextrose solution administered by the rectal drip. Among 283 patients there were 5 mild cases of peripheral neuritis and, while there were no fatalities from its use 1 patient developed convulsions two days after termination of therapy and lapsed into a stupor for forty-eight hours. In 2 other cases there were mild cerebral symptoms, all 3 interpreted by them as varying grades of hemorrhagic encephalitis. Therapeutically, of 176 patients followed for at least a year 69 received the full dose of 1,200 mg and 86 per cent were serologically negative and clinically well. Of another 107 patients receiving less than the full dose of mapharsen for one reason or another, 74 per cent apparently were cured.

Rightfully stimulated by the results, this form of therapy was immediately taken up by other workers in various centers. Thus Dr D. C. Elliott of the United States Public Health Service reported to Dr Herbert Rattner³ of Chicago that more than 1,150 patients had been treated by this method under the auspices of the Middle Western Cooperative Group, and still more recently Dr R. A. Vonderlehr in a personal note said that some 1,700 patients had received the intravenous drip in a group of midwestern clinics through November

1942 and several hundred more since Dr Rattner was one of the earliest to evaluate the possibilities of the technic. He has completed the study of 481 cases at the Cook County Hospital. His technic was above reproach and there were no fatalities, though he did observe an acute glomerulonephritis, anuria, uremia, hepatitis, ileus and pericarditis. There were also 3 cerebral reactions, 2 of them encephalopathy, fortunately all with recovery. Rattner observed 12 to 15 per cent of failures from one five day treatment and he believes this has been materially reduced in his later cases through simultaneous use of soluble bismuth—the latter with no added reactions. Dr Earl Osborne⁴ of Buffalo has thus far treated between 250 and 300 cases, the first 100 prior to Jan 1, 1942. There was 1 fatality from hemorrhagic encephalitis in a young healthy girl. There were 2 other near fatalities with recovery, 1 of them a male alcoholic. Dr Osborne quotes Dr Udo Wile with having made the keen observation that women either before or during the menstrual period should not be treated with the intravenous drip as at this time the vascular structures would be more affected by a vasculotoxic drug. He states that this was the condition with his patient. He feels that for a large city hospital clientele this is the preferred form of therapy. With other methods two thirds of the patients have absconded before the first year of treatment, whereas at the end of the first year the spinal fluid was not positive in any of his first hundred cases. There have been 2 infectious relapses and 3 serorelapses, a really remarkable result.

Dr Henry Michelson⁵ of Minneapolis, a very careful and skilled clinician, has had two deaths and one near death in 45 cases, making him rather hesitant about intravenous drip therapy. He feels it is too dangerous and that intervals between injections—perhaps with some form of combined fever therapy—is preferable. He leans more to biologic than to chemical therapy.

Drs Guy and Jacobs⁶ of Pittsburgh have treated 21 patients with no ill effects. Dr Udo J Wile⁷ of Ann Arbor states that he has thus far treated almost 200 cases over a period of two years. There have been no severe reactions and he is favorable to it as the best for rapid treatment procedures.

Dr Paul O'Leary⁸ of Rochester, Minn., has done no work with intravenous drip therapy, feeling that the incidence of serious complications and death was too great. Dr John Stokes⁹ of Philadelphia has done little with it. The personnel problem and setup were difficult for this additional endeavor along with the heavy teaching schedule. Moreover, an aplastic anemia almost in the inception of the work did not help his attitude. They are doing some work with chemotherapy plus fever, using Warren's bath tub technic, but here again the shortage of personnel is difficult. Dr Charles Dennie¹⁰ of Kansas City, Dr Joseph Earl Moore¹¹ of Baltimore and Dr Dudley Smith¹² of University, Va., have not been using the procedure. Dr Loren Shaffer¹³ of Detroit feels that the five day intensive therapy has a very definite place, particularly for the uncooperative

clinic type of patient, but does not think it is universally applicable in all cases of early syphilis. But more in regard to his views later.

Following the report of Baer, Chargin, Hyman, Leifer and others in November 1940 this form of treatment was employed in our City Hospital clinic on 5 patients with early syphilis. They were given daily injections of 1 mg of mapharsen per pound of body weight for five days. Half of the total dosage was dissolved in 500 cc of 5 per cent dextrose in distilled water and given by rapid intravenous drip every morning and afternoon. One patient experienced a rather severe headache after the second injection on each of the first three days of therapy. Aside from this there were no reactions.

Three of the patients have been followed for fifteen months or longer. All had strongly positive serologic reactions when the treatment was given. The serologic reactions became negative in from three to five months after the therapy. One was seronegative at fifteen months, another at eighteen months and another at thirty months after completion of the treatment. Two patients were lost from observation. Because of reactions observed in other centers the technic was discontinued for the time, even though we had had no difficulties.

Recently we have treated 5 patients with daily injections of 0.200 to 0.240 Gm of mapharsen in 2,400 cc of 5 per cent dextrose in distilled water by slow (twelve hour) intravenous drip for five days. All these patients experienced rather severe phlebalgia. Other than this there were no complications.

In August 1940, moreover, 6 patients with early syphilis were given daily injections of 1 mg of mapharsen per pound of body weight in 1,000 cc of 5 per cent dextrose in distilled water by rapid intravenous drip each morning for five days. There were no untoward reactions with this Shaffer technic, which will be described later.

Two patients have been followed for over two years. Both were dark field positive and seropositive when the therapy was given. The serologic reaction on both became negative forty to fifty days after the therapy and remained so twenty-four months later. One, who received a total of 600 mg of mapharsen, was examined thirty-two months after therapy and found to have strongly positive serologic reactions for syphilis but there were no signs of a secondary relapse. Four patients were lost from observation.

Stimulated by the results from the intravenous drip technic others have adopted a somewhat different technic, the idea in all of them being the introduction of as large and yet safe an amount of trivalent arsenical as the patient with acute syphilis can stand in a limited amount of time.

Thus Schoch and Alexander¹⁴ in Dallas, Texas, have treated over 350 patients. In the beginning they gave twenty daily intravenous injections of 0.060 Gm of mapharsen. However, the vast majority were treated with ten consecutive daily injections of mapharsen, each 0.120 Gm, the total dosage being 1.200 Gm. There was hemorrhagic encephalitis with death in 1 case and 2 other cases of mild encephalitis with recovery. The only other severe reaction was a case of icterus with recovery. Schoch's reappraisal of a group of 103

patients treated with the ten day syringe method five months after the article was written, showed 83 per cent satisfactory results, 12 per cent failures and 15 per cent still remaining seropositive. They are now using the Eagle technic and think there is a greater margin of safety than with the ten day technic. It is his impression, however, from preliminary results, that they were better with his technic. Time will tell the story. They have since recorded 10 cases of rein-

TABLE 1—*Detroit Plan (Early Cases Only)*

- 1 Mapharsen (0.06 to 0.07 Gm according to body weight) three times weekly for twenty doses (six and two thirds weeks)
- 2 Bismuth sub salicylate 0.2 Gm twice weekly for eight doses (four weeks)
- 3 Mapharsen twice weekly for ten doses (five weeks)

fection. Four patients sustained reinfections following orthodox antisyphilitic therapy. The known period of clinical and serologic negativity was four and one-third years for 1 patient and greater than five for 3. Six of the 103 patients noted in the second report sustained reinfections following ten day intensive arsenotherapy for early syphilis (1.2 Gm of mapharsen). Dark field and quantitative reagin titer findings were furnished to support clinical observations. All the cases were observed by them in both infections and in 1 of them it was believed that there had been three infections in one year. The authors feel that, following intensive arsenotherapy, reinfection is more frequently observed than formerly.

Dr Loren Shaffer¹⁵ in Detroit tried five daily doses of approximately 1.2 mg of arsenoxide per pound of body weight administered in 1000 cc. of 5 per cent dextrose and given by intravenous drip. This required about seventy-five minutes. The maximum daily dose was limited to 0.180 Gm and the total dose for the course ranged from 0.750 to 0.900 Gm. Some 430 cases have thus far been treated, there have been 2 cases of encephalitis, 1 of them fatal. Later the dosage of arsenoxide was slightly lowered. The incidence of encephalitis was about the same as has been observed with other technics. The incidence of relapses, both clinical and serologic, was somewhat high. In January, 1942 an ambulatory intensive method¹⁶ of treatment was adopted by the Detroit Department of Health. It is used only for patients with primary and secondary syphilis who have refused hospitalization for five day treatment or have been considered poor risks. It calls for thirty mapharsen and eight bismuth injections over a period of approximately four months. It is too early to announce results of its use. Dr Shaffer has been one of the earliest and most vigorous proponents of intensive therapy for early syphilis.

With the Detroit plan (table 1) a spinal fluid examination should be made during the bismuth course or at least on the completion of treatment. After treatment is finished early cases are rechecked at monthly intervals for one year and early latent cases every three months. Thereafter, if negative, both types are checked every six months. Naturally, with early cases a complete physical examination is also in order. If the serologic reaction remains positive for one year, further study is in order.

Shaffer's plan is perhaps somewhat more intensive than the Army plan issued by the Surgeon General of the Army in circular letter 74. Much the same follow-up

and routine is used in the Army plan as with the Shaffer Detroit plan.

The Army plan (table 2) calls for forty mapharsen and sixteen bismuth injections in a period of twenty-six weeks.

Shaffer is already disappointed with the Detroit plan because of the high percentage of patients lapsing therapy. Consequently he thinks the five day hospital plan is preferable, though it is hardly suitable to all cases and must be carried out by expert personnel. He thinks that, until more experience can be gained, when one is dealing with the ordinary run of mine clinic patient, who is none too cooperative, either the Army plan or the Detroit plan should be adopted for general use.

Dr A. B. Cannon¹⁷ of the Vanderbilt Clinic in New York still has great faith in arsphenamine, and since July 1941 he has completed the treatment of 226 persons. The patients are hospitalized and of the 189 whom they have been able to follow 123 had negative serologic tests within a period of two weeks to one year, the average being three and one-half months. The plan of treatment has been changed four different times. The present one necessitates four daily intravenous injections of arsphenamine in concentrated form. The total dosage runs from 3.0 Gm minimum to 3.6 Gm maximum. Patients are started on large doses, getting almost half of their treatment in the first two days. There have been 2 cases of encephalitis, with survival in both, 2 of moderate neuritis and 3 cases of icterus, 1 of them a toxic hepatitis. There have been twenty-five mucorecurrences and two persisting serologic reactions.

Eagle and Hogan undoubtedly correctly approached the treatment of early syphilis by the experimental route,

apply with the other and vice versa. One very important item that they have brought out is with regard to "cure" in rabbit syphilis. They find that "until time limits within which infectious relapse may occur in the rabbit have been more clearly defined the absolute curative dose of arsenicals in rabbit syphilis cannot be determined by lymph node transfer."

Even data as to the relative efficacy of various treatment procedures must be interpreted in the light of the time allowed to elapse between treatment and the following lymph node transfer. Their study showed that six months after treatment in a large series of rabbits, apparently cured at three months as judged by node transfer, 37 per cent of them were still infectious.

Apparently the disease was actually quiescent at three months after treatment but not cured. Is there a lesson for us in this in considering human syphilitic therapy? They find in rabbit syphilis that the time factor has much to do in determining the toxicity of a treatment system. Thus the same treatment of syphilis may be intensified, the treatment period may be shortened by various methods, but they have definite and predictable effects on the margin of safety. In the short term intravenous drip, treatment is concentrated within a few days but the mapharsen is given in a continuous slow infusion for many hours daily. Such a slow infusion is less toxic than single daily syringe injections of the same amount of mapharsen, but it is only slightly less toxic than multiple syringe injections (e.g. four times daily) distributed over the same time period. Moreover, in rabbits the therapeutic efficacy of mapharsen given by slow intravenous drip was usually less than if the same amount of the drug was given by repeated syringe injections, whether triweekly, daily or four times daily. Another method of intensifying treatment is to give the same number of injections but at shorter intervals. Thus, instead of twenty weekly injections one may give injections three times weekly for seven weeks daily for twenty days or twice daily for ten days. It is clear that, the shorter the time interval between injections, the more pronounced will be their cumulative toxicity. The intravenous drip was significantly less effective than multiple syringe injections administered over the same time period in rabbit syphilis. An appreciable condensation of treatment beyond that permitted by triweekly, daily or multiple daily injections can be accomplished only at the cost of safety by an arbitrary decrease in the total number of injections.

Eagle and Hogan have suggested a clinical adaptation of their studies in human beings with early syphilis. The patients are given a weekly intramuscular injection of bismuth subsalicylate 0.2 Gm and triweekly intravenous injections of mapharsen for six, eight, ten or twelve weeks. Thus far, March 5, between 1,900 and 2,000 patients have been treated at various cooperating clinics throughout the country. In the Cleveland area we have treated the patients at the University Hospital and Charity Hospital with the eight week method and at the Cleveland City Hospital with the ten week method. Naturally it is too early to evaluate the results of this therapy, though it appears to be quite promising. The great difficulty has been to keep the patients on regular treatment. At the first two institutions a total of 114 patients have thus far been treated and at the City Hospital a further 95, of whom 107 have completed their course of treatment. Of these 22 missed no treatments, 34 missed one to five treatment days, 20 missed six to ten treatment

days and 31 over ten treatment days, a total of 107 patients. Unfortunately 34, or 16.2 per cent, have already been lost from observation or treatment, fortunately, 11 of these were after completion of therapy, but this does not help future evaluation of the data. Moreover, in 12 of the cases under the eight week regimen and in 12 under the ten week regimen it has been necessary to discontinue the treatment because of reactions. Seventeen were much alike, characterized by nausea, vomiting, general malaise, photophobia, chills and fever from 39 to 40 C (102.2 to 104 F). Shortly after onset of the symptoms the patients showed some conjunctival injection and edema of the face. These symptoms came on after the fifth or sixth injection and from nine to twelve days after the first injection of mapharsen. One patient developed an icterus lasting fifteen days. Another patient after the fifth injection developed a daily asymptomatic, spiking temperature to 39.5 C (103 F). He was found to have moderately far advanced pulmonary tuberculosis. Following this case a preliminary chest plate was taken in all cases on intensive therapy.

To illustrate what we speak of as our "fever-conjunctival injection-facial edema syndrome"

A Negro woman with early mucocutaneous syphilis was started on intensive therapy on July 9, 1942. After the fifth injection of 0.06 Gm of mapharsen she had a slight headache. Several hours after the sixth injection of mapharsen she developed nausea and vomiting followed by circumocular edema, conjunctival suffusion, headache, weakness and fever of 39 C (102.2 F). It then took five days for her fever to subside. A week after onset of this reaction she received 0.01 Gm of mapharsen with immediate recurrence of the previous symptoms. Twelve days after this reaction 0.1 Gm of neosphenamine intravenously produced the same reaction and, in addition, profound muscular weakness. She recovered from this fairly well over the period of a week. Subsequently she received eight injections of iodobismutol every week. Three months after the original reaction 0.01 Gm of mapharsen produced no untoward result. A few days later she moved to Kansas and has not been heard from since.

There has been one relapse at City Hospital, mucocutaneous in type, in a woman who during the course of treatment missed thirteen treatment days. There was also one in a woman under the eight week regimen. She also had missed twenty-four treatment days.

There is a further meningitic type of relapse.

A man aged 57, an Italian, was seen with a chancre and early mucocutaneous syphilis which was dark field positive. At the beginning of therapy on July 16, 1943 his Wassermann and Kline reactions were 4 plus. He then received regular therapy for eight weeks with the exception of one visit, which he lapsed. At the completion of therapy his Wassermann reaction was 4 plus, Kline diagnostic 1 plus and Kline exclusion 3 plus. Six weeks after therapy his Wassermann reaction was 1 plus, Kline diagnostic negative and exclusion 2 plus. Two months after therapy his Kline diagnostic and exclusion reactions were negative. Seven weeks after therapy his spinal fluid showed 300 cells, positive Ross-Jones, 432110 colloidal mastic curve and 4 plus Wassermann reaction in 0.5 and 1.0 cc.

FEVER THERAPY IN SYPHILIS

We now come to another milestone in the therapy of syphilis—fever treatment. Wagner Jauregg was the first to use a form of hyperthermia, malaria, for treating dementia paralytica. Later this treatment was tried in early syphilis and found to be unsuccessful. From malaria therapy we have drifted to the use of other fever producing implements, foreign protein therapy, e.g. typhoid-paratyphoid intravenous injections, hot baths, the inductotherm and the hypertherm. Their

value in central nervous system syphilis is unquestioned, and investigators have naturally turned to them in the treatment of early syphilis. It was an American dermatologist J. F. Schramberg¹⁹ who as long ago as 1926 reported the beneficial effects of hot baths in experimental rabbit syphilis. In 1935 Epstein and Cohen²⁰ and in 1936 Neumann Lawless and Osborne²¹ found such treatment to be ineffective in human syphilis. This has been confirmed by Bork, Carpenter, Jones, Kampmeier, McCann, Warren and Williams²² and by Simpson, Rose and Kendall.²³ However, when this fever therapy is combined with chemotherapy it may be a different story. The interested reader may consult the recent review of Simpson, Kendall and Rose.²⁴ These authors²³ have a group of 27 patients with early syphilis observed for four to eight years who have had no clinical or serologic relapse. They received fever therapy consisting of either twelve three hour or ten five hour sessions (rectal temperature 105 to 106 F) administered once or twice weekly. With each treatment an arsenical preparation (neovarsphenamine 0.3 Gm or mapharsen 0.04 Gm) and a bismuth compound (containing 0.2 Gm of metallic bismuth) were administered. Following the fever therapy, injections of the chemotherapeutic agents were continued for an additional twenty weeks, injections of the arsenic and bismuth being concurrent. They further report on a series of 23 patients observed from six months to two and one-half years. The patients were given a preliminary injection of 0.25 Gm of bismuth subsalicylate then placed in a hypertherm and given a ten hour session of artificial fever at 106 F. Mapharsen was used in all the cases. Two patients received 240 mg by intravenous drip during the period of fever at 106 F. This was abandoned in favor of administration of injection by the syringe method in 60 mg doses at intervals of three hours. Six patients were given two injections (120 mg), five received three injections (180 mg) and 3 received four injections (160 mg). The first injection was given when the rectal temperature first reached 106 F, the second at the end of the third hour, the third at the end of the sixth hour and the fourth at the end of the ninth hour. No other treatment was given. Serologic reversal was dependent on the height of the initial pretreatment titer. It occurred in from twenty-one to one hundred and seventy-six days. The authors state that the number of patients is small and the period of observation insufficient to permit adequate clinical evaluation. They believe, however, that the results are sufficient to justify further investigation. There can be little doubt about the value of their observations, and they are to be congratulated on their conservative approach. As we understand it, a quite similar procedure is being carried on by Dr. Nathaniel Jones and

S. L. Warren²⁵ at the Duval County Hospital, Jacksonville, Fla., where they have treated well over 100 cases, and at the Chicago Intensive Treatment Center under the direction of Dr. H. Worley Kendall,²⁶ where they have in a period from October 1942 to date treated a total of 350 or 400 patients. At the latter institution treatment consists in eight hours of fever at 105.6 to 106 F and there is given arbitrarily to men 0.090 Gm of mapharsen and to women 0.060 Gm. One third of the mapharsen is given when the temperature reaches its height and one third at approximately three hours and six hours afterward. They also administer 1.5 cc of 10 per cent suspension of bismuth subsalicylate before treatment is started in the morning. Dr. Kendall furnished the information thus far available and urges extreme conservatism until sufficient material has been treated and carefully evaluated. He is quite emphatic that their work is still in the experimental stage. They plan on gradually increasing the dosage.

THE COMBINED SYRINGE METHOD THERAPY PLUS FEVER

In 1937 Thomas and Wexler in New York City²⁷ increased the number of injections of mapharsen from one to two a week and by 1938 to three a week for four weeks for all patients with early infectious syphilis. In the light of the intensive therapy they determined to attempt rapid massive treatment without the continuous drip—their facilities at Bellevue did not easily allow the latter. Later they stepped up their dosage still further using the standard syringe method for injection giving at first 0.060 Gm of mapharsen twice daily for ten days, the same dose, 1.200 Gm, used by the Mount Sinai group. Later they tried 0.100 Gm twice daily, which worked nicely until the 111th patient, who had a fatal encephalitis. Since then they have endeavored to keep the total dosage of mapharsen under 0.800 Gm in a period of ten days. Dr. Thomas feels, however, that such a dosage to be therapeutically effective must be supplemented with fever. He states that the program they have used now for six months and which is quite satisfactory consists of ten daily injections of mapharsen 0.060 Gm each with four fevers induced by typhoid vaccine. The fevers are given as a rule on the second, fourth, sixth and eighth days. The dosage is varied somewhat according to weight. Originally Thomas felt that fever prevented toxic reactions²⁸ of arsenical drugs. He later reversed this opinion.²⁹ Dr. Thomas thinks that intravenous drip therapy has no advantage over the syringe technic and certainly their results are even as good. Intravenous drip therapy is also probably more toxic. He has also treated 50 patients with Eagle and Hogan's three injections of mapharsen a week for six or eight weeks. He thinks the treatment is therapeutically effective but that it is a most unsatisfactory plan and impractical in their work in which they have so many Negroes and irresponsible patients. To this we heartily agree. All their work has been most painstaking, very carefully planned and carried through and presents a most convincing argument in favor of the syringe technic plus fever treatment.

COMMENT

It is fair to say that from the data given here evidence is presented showing that early syphilis is being cured by intensive treatment methods, whether it be intravenous drip, the syringe technic, multiple injections of Eagle, or fever therapy and intravenous drip or syringe treatment plus fever. The patients are not only cured but, as Schoch and Alexander show, they are even being reinfected in appreciable numbers.

Stokes³⁰ has recently reviewed the difficult problem. He points out that a new system of treatment of syphilis must equal or surpass the curative expectancy of the older ones, lead to less infectious relapses, cure more mothers and protect more children and lessen the incidence of cardiovascular and central nervous system syphilis. On the other hand, when we talk about the relatively benign character of much early syphilis, 40 to 50 per cent, and the fact that with relatively small amounts of treatment, if it doesn't disturb the defense mechanism, this may even be raised to as high as 70 per cent, here we are completely ignoring the public health problem of syphilis, especially in wartime. He quite properly insists that evaluation of a system of treatment requires two to four years as far as relapse is concerned and ten years for evidence of progression. A new system must be cheap and rapid, control the lapse problem and allow treatment of more persons per unit of time, personnel and equipment. All these arguments are, of course, in favor of intensive methods though, as Stokes notes, the man cured with intravenous drip or with fever plus chemotherapy must be followed afterward even as much as his lady friend treated by the longer but safer eighteen months method. And too he states that with intensive methods wherein patients are even paid for follow-up visits the loss rate is 17 per cent and in some clinics 6 to 20 per cent up to six months. He thinks that long term treatment in the modern syphilis clinic is carried through in 25 per cent of the early cases and 50 per cent ultimately receive satisfactory irregular treatment. Moreover, that in really good clinics with effective case holdings it may be raised to 50 per cent with 70 to 80 per cent ultimately receiving satisfactory irregular treatment. In this connection one should remember that we are not dealing with a half dozen top clinics but with the run of mine clinic throughout the United States. How well is this clinic holding its cases? It is not necessary to answer the record is bad, spelled with a capital B. He is probably right in his contention that the percentage of relapse is about the same with intensive methods as with conventional treatment. We agree that for the present, at least, intensive therapy should be reserved for relatively acute syphilis—not later than early latent.

We now come to the real problem with intensive methods. Stokes says that for 4,871 patients treated with all the intensive methods there was a mortality of 1/220 and a morbidity of nonfatal encephalitis of 1/160. Shaffer makes the figure for mortality 0.3 per cent. It is true that with older methods encephalitis is a very rare, he puts it 1/20,000. Deaths from mapharsen are thus a demonstration of millions of doses. The rate is probably one hundred to two hundred from older methods. In reply to this the ultimate mortality or morbidity of an number of early uncooperative syphilitic patients take a few treatments and lapse. And, too, how

new infections do they pass on and thus keep the syphilitic ball rolling? How many mothers and how many babies are infected by them before their disease gets so old that it is no longer transmissible? Moreover, would not such an intensive technic be a partial answer to our expert help problem in our clinics? The patient receives his treatment and then is through except for follow-up and occasional examinations.

Vonderlehr and Usilton³¹ have recently analyzed the 1,895,778 serologic reports of men aged 21 to 35 who were examined under the Selective Service Act of 1940. The rate of prevalence of syphilis among the entire male population between 21 and 35 is estimated to be 47.7 per thousand. However, the rate of prevalence among Negro selectees is 253.3 per thousand and among white selectees 17.4 per thousand. Moreover, if one turns to urban centers in the South it is found that the rate of prevalence among Negro men ran 413 per thousand in Florida, 407 in Georgia, 358 in Arkansas, 339 in Maryland, 431 in Mississippi, 384 in Texas, 417 in South Carolina, and so on. Unfortunately, these data present the crux of the whole syphilis problem. The rate of prevalence is highest among the most ignorant and least cooperative part of our population. In the Cleveland district it is just this portion of our patients that are hardest to hold, that are easiest lost, in fact so effectually that even their draft boards cannot find them. The common complaint from all workers in syphilotherapy is difficulty in finding the uncooperative patient. A few treatment

With those forms of treatment hospitalized and receives his at least one or she, skin, numbed to a small routine amidst war in which syphilis, for the daily syphilis, be the intensive method medical. Stokes dose of two massive injections the answer Eagle technic treated when Thomas and mapharsen C typhoid on the five day bismuth intravenous chemotherapy that such experts in treatment points at to do it.

THE SYNTHETIC ESTROGEN OCTO-
FOLLIN (IN OIL)

REPORT OF CLINICAL INVESTIGATION

ALVIN RAY HUFFORD, M.D.

GRAND RAPIDS, MICH.

Although there is no doubt concerning the efficacy of estrogen therapy in the female climacteric there is considerable uncertainty about the optimal preparation to be used. The criteria for effective treatment are two: subjective relief and vaginal smear response. To the practitioner interested primarily in the welfare of his patients the relief of symptoms is of more importance and rightly so, than the results of any objective tests which may be made. Until such time as some investigator has at his disposal a group of young women from whom all ovarian tissue has been removed by surgical means evaluation of the activity of estrogens in human therapy by the vaginal smear technic can never be a precise laboratory procedure. It is true, of course that some estimate of the degree of response to the therapy can be gained by the smear technic, and we have used such tests to supplement our subjective findings. In choosing an estrogen the physician must consider also other factors—cost (to him or to the patient) of adequate therapy and the extent to which toxicities or side reactions occur following oral or parenteral therapy.

There would seem to be nothing to be gained by a lengthy discussion here of the voluminous literature representing the experiences of investigators and clinicians with diethylstilbestrol. The report of the Council on Pharmacy and Chemistry¹ together with the review articles mentioned therein must be familiar to all workers in the field. It would appear to be universally accepted that diethylstilbestrol is a remarkably effective estrogenic drug when administered either orally or parenterally. There has been considerable controversy, however, over the degree to which toxicities or side reactions are manifest during the administration of this synthetic estrogen.

During the last year I have been using a new synthetic estrogen, octofollin,² on a large group of climacteric patients. This compound, which is not a derivative of stilbestrol, has the chemical name 2,4-di-(para-hydroxyphenyl)-3-ethyl hexane. The steps leading to the development of this compound have been outlined by Blanchard, Stuart and Tallman,³ and reports of the physiologic studies of this estrogen were presented in 1942 from the same laboratory.⁴ Freed and his co-workers,⁵ and Greenhill⁶ reported satisfactory results with this compound in menopausal patients and indicated that it was much less toxic than stilbestrol or hexestrol. Murphy⁷ reported that satisfactory results have been obtained with the use of octofollin in the relief of the symptoms of the menopause, in gonorrheal vaginitis in children and in the suppression of lactation.

Jaeger and his co-workers⁸ mentioned its use in gonorrheal vaginitis and believed it to be a most efficient estrogen.

EXPERIMENTAL MATERIAL AND RESULTS

It was my intention at the outset to test the efficacy of octofollin both by oral and by parenteral administration. At the start, the memory of side reactions with stilbestrol therapy resulted in overcaution in the oral administration of this new synthetic, and as a consequence the clinical response was not encouraging. However, not one of the patients reported any untoward reaction of any kind during the course of therapy. The average daily dose by mouth in this series of patients was 1.0 mg. Therapy with octofollin in oil was begun by deep intramuscular injection and the results were very satisfactory. In all the cases to be reported here the estrogen was administered by this route. Therapy was given to a series of 21 women with various symptoms indicative of estrogen deficiency. The summary of the results on these cases, giving dosage data is given in the accompanying table. Not one of these patients ever demonstrated any toxic symptoms or local reaction at the site of injection. Gastrointestinal disturbances which were not at all uncommon with diethylstilbestrol were absent, and there was no evidence of pelvic pain or discomfort, no vaginal bleeding during therapy and no dermatitis. The amount and frequency of the dosage are determined by the type of patient and the severity of the symptoms.

The cases in this series ranged from mild menopause types to those with the more severe symptoms of the surgical menopause. The majority of the patients had similar symptoms with an average degree of severity.

In the accompanying table the five starred patients had liver function tests. Four of these showed completely normal function both before and after considerable therapy. The fifth patient, D. M., having latent syphilis and chronic cholecystitis, exhibited a 2 plus cephalin flocculation test at the beginning of therapy and there was no change following six months of octofollin therapy.

Vaginal smears were done on all the patients shown in the table. I have been using the iodine staining reaction as a measure of estrogen response. In the majority of cases there was a moderate to pronounced reduction in the number of iodophilic cells before therapy. Following therapy there was an improvement in the appearance of the smear in almost all cases, although complete cornification was observed in but 2 cases. It is quite apparent that definite, or complete, relief of menopausal symptoms can follow estrogen therapy without the necessity of producing completely cornified vaginal smears.

Space does not permit the insertion of detailed protocols on all the patients. One typical protocol is given here, however, with the idea that it will give a better idea of the way in which treatment was carried out on the average patient.

E. W., white, aged 44 except for a sacroiliac strain and some hypertrophic arthritis of the sacroiliac joint had no illness or operation. When first seen in October 1941 the patient complained of low backache also spells of hot flashes and vertigo exhaustion and at times some precordial discomfort. The physical and x-ray examination revealed no serious pathologic condition, however, there was some moderate hypertrophic reaction of the right sacroiliac joint. The Kahn reaction, blood count and urinalysis were essentially negative. Liver function tests

were made. The cephalin-cholesterol and bromsulphalein tests were negative, and four weeks after the use of the synthetic estrogen octofollin the tests still showed completely normal liver function. The menstrual history was normal. In the past six months the periods had been growing more scanty and becoming a little irregular. Vaginal examination showed a perfectly normal cervix and fundus and no evidence of tumors or inflammation. The vaginal smears revealed quite a few round or oval atrophy cells.

The patient received therapy of natural estrogenic hormone 10,000 international units parenterally twice a week for six injections. This was followed by a definite symptomatic improvement for four or five weeks. The vaginal smears made during the time of greatest improvement showed little cornification with the atrophy cells still present to a moderate degree, notwithstanding the subsidence of clinical symptoms. With the

The hypertension which seems to be present in certain menopause patients seemed also to be improved with octofollin therapy. This is particularly noted in one patient, M. L. M. in the table, whose blood pressure before the start of treatment varied between 180/110 and 200/120. After three months of therapy the blood pressure was 150/90 to 160/98. Similar decreases in blood pressure, though less striking, were noted in other patients in this series.

COMMENT AND CONCLUSIONS

Octofollin in my experience provides prolonged beneficial effects. This means sustained as well as additional comfort for the menopausal patient.

Summary of the Clinical Results of the Investigation of the Action of Octofollin

Patient	Age	Conditions and Symptoms for Which Treatment Was Given	Dose and Frequency	Clinical Results
G. H.	45	Natural menopause, hot flashes, sweats, palpitation	2 mg twice a week for 3 weeks then 2 mg once a week for 6 weeks	Almost complete control of symptoms
J. G.	44	Postoperative menopause, hot flashes, depressed feeling, exhaustion	5 mg twice a week for 4 weeks then 5 mg once a week for 8 weeks	Complete control of symptoms
C. W.	37	Early menopause, scanty irregular periods, hot flashes, nervousness, low basal metabolic rate	2 mg twice a week for 3 weeks then 2 mg once a week for 6 weeks	Complete control of vasomotor disturbances
G. I.	48	Natural menopause, menses irregular, hot flashes, depression	2 mg once a week for 8 weeks	Pronounced clinical improvement in symptoms
H. DeV.	78	Approaching menopause, scanty periods, precordial pain and heart consciousness	5 mg once a week for 5 weeks, then 5 mg every 2 weeks for 3 months	Almost complete control of symptoms
H. M.	51	Postmenopausal, no hot flashes, but pressure pain in head and neck	5 mg once every 2 to 3 weeks	Complete control of subjective symptoms
P. W.	42	Dilation and curettage and x-rays to uterus for menorrhagia following this depressed feelings and headache, no flashes	5 mg once a week for 4 weeks then 5 mg once every 2 to 4 weeks	Partial relief of exhaustion and back ache
F. S.	39	Hot flashes and exhaustion following high voltage x-rays	2 mg once a week for 7 weeks	Complete relief of symptoms after 4th dose and no return of symptoms until 3 months after last injection
F. S.	46*	Natural menopause, severe and frequent hot flashes, day and night	5 mg twice a week for 3 weeks then once a week for 4 weeks now once every 4 to 6 weeks	Complete control of symptoms vaginal smear returned to more normal appearance
C. M.	52	Menopause, menses scanty and irregular, severe hot flashes, sweats and choking feeling, palpitation of heart	5 mg twice a week for 1 month then once every 1 to 2 weeks for 4 months	Complete control of symptoms with the frequent doses and fair control with doses every 2 weeks
L. D.	47	Menses irregular and infrequent for past year, exhaustion, nervousness and few hot flashes	5 mg a week for 1 month then 2.5 mg every 2 to 3 weeks	Satisfactory control of subjective symptoms and improvement in vaginal smear
R. A.	52	Two year postmenopausal, exhaustion and pressure in head	5 mg once every 4 to 6 weeks as necessary	Almost complete control of symptoms for 4 to 6 weeks with one 5 mg dose
M. H.	52	Hysterectomy in 1934, hot flashes and vaginal irritation since in varying degree	5 mg every 1 to 2 weeks for 3 months, then once a month	Quite complete relief of symptoms if dose is given once a month
F. W. K.	52	Menopause, severe hot flashes since menses ceased in 1941, headache and bloating	5 mg a week for 12 weeks, then once a month	About 50 per cent relief in subjective symptoms
A. B.	36	Hysterectomy in 1941, severe and frequent hot flashes in 1942	5 mg a week for 1 month, then every 3 to 4 weeks	Satisfactory relief of hot flashes for 2 to 4 weeks with 5 mg
R. B.	33	Miscarriage in 1941 followed by dilation and curettage, hot flashes and depression began in 1942	5 mg twice a week for 8 weeks then once a week for 2 months	Hot flashes stopped after 34 days after first injection, relief of depression with 20 injections
H. V. D.	40	Hot flashes, depression and irregular menses	2 mg once a week for 2 months	Quite satisfactory reduction in symptoms for 6 months after treatment
M. L. M.	51*	Menopause, infrequent and scanty menses, hot flashes	5 mg once a week for 1 month, then every 2 to 5 weeks for past 4 months	Almost 100 per cent relief of hot flashes
D. M.	50*	Menopause, hot flashes, latent syphilis, treated, chronic cholecystitis, intolerant to diethylstilbestrol	2 to 5 mg at irregular intervals	Control of hot flashes with 2 to 5 mg for varying lengths of time. 5 mg will stop hot flashes 2 to 3 weeks
E. W.	44*	Early menopause, hot flashes, night sweats, dizzy, intolerant to diethylstilbestrol	2 mg twice a week for 1 month then 5 mg a week for 6 to 8 weeks	Complete relief of symptoms, complete cornification of vaginal smear
H. L.	44	Early menopause, flushing, sweating, headaches	2 mg twice a week for 6 weeks then 2 mg a week for 6 weeks	Gradual and complete in 6 weeks with cornification

return of symptoms such as hot flashes and vertigo the patient was placed on diethylstilbestrol orally 0.5 mg per day. The symptoms subsided within a few days, but the patient became nauseated and had a sense of soreness and fullness of the breasts after eight days, so that it became necessary to discontinue the therapy. The injection of diethylstilbestrol 0.5 mg twice a week also gave clinical improvement but also created the toxic symptoms as before and was discontinued.

In May 1942 the patient was placed on injections of the synthetic estrogen octofollin, receiving 2 mg twice a week for one month without there being the least sign of toxic symptoms. She received thereafter 5 mg a week and later every two weeks for two months more. Complete relief of hot flashes, sweats and dizziness resulted and the patient generally was better after the fourth injection. This improvement continued for over six months without further injection and with no return of symptoms. An apparent improvement in the arthritic condition was also reported by the patient.

Undesirable side reactions, such as headache, nausea, vomiting, dizziness, soreness of the breasts, pelvic pain and excessive or frequent uterine bleeding, were not encountered in my experience. Such reactions were encountered frequently in therapy with diethylstilbestrol both by the oral and by the parenteral routes of administration.

In general also there seemed to be quite a decided improvement in the vague arthropathies and hypertension associated with the menopausal syndromes in this series of patients.

The results given here indicate that the new synthetic estrogen octofollin, when administered parenterally in oil to menopausal patients, is an effective estrogen and is nontoxic in therapeutic doses.

Since Dodds and his associates¹ synthesized the estrogenic substance diethylstilbestrol in 1938 numerous clinical studies have demonstrated that this compound is a powerful and therapeutically effective estrogen when administered either by injection or by mouth. Many investigators have shown that it may produce some undesirable reactions. The commonest clinical objection to diethylstilbestrol has been nausea, and in various series from 10 to 60 per cent of the patients treated have complained of this possibly toxic reaction. Usually nausea can be avoided by reducing the dose² or by giving the medication at bedtime³ or by using interrupted treatment.⁴ A few patients do not tolerate even small doses and Finch⁵ has suggested that nausea may be an allergic reaction. Infrequent occurrence of vomiting, headache, vertigo, abdominal distress, diarrhea or dermatoses has been reported following the administration of diethylstilbestrol. Thus the dosage and therefore the therapeutic effectiveness of this synthetic estrogen is limited to some extent by possible toxic gastrointestinal disturbances and occasionally by other side reactions.

Attempts have been made to produce stilbestrol modifications and to synthesize other estrogenic compounds which would not cause nausea or the other untoward symptoms sometimes occurring with diethylstilbestrol. Geschickter and Byrnes⁶ demonstrated that stilbestrol monomethyl ether is an estrogen of clinical value, and Elden⁷ reported that only 10 per cent of his patients received no benefit from this medication. Abarbanel,⁸ however, found that when stilbestrol monomethyl ether was given in doses estrogenically equivalent to those of diethylstilbestrol the incidence of nausea was similar with the two compounds. According to Bieren and Compton⁹ dihydrostilbestrol (hexestrol) is a powerful estrogen, but its effective dose in adults was ten times that of diethylstilbestrol, and nausea occurred in over 8 per cent of their cases.

New synthetic estrogens which are not related to the natural estrogens or to the stilbenes have been reported recently. Robson and Schonberg¹⁰ dem-

onstrated that triphenylethylene produced complete estrous response in ovariectomized mice and found this preparation to have a prolonged effect. Later these authors reported good estrogenic effect in animals with α -di-(*p*-ethoxyphenyl)- β -phenyl bromoethylene.¹¹ Macpherson and Robertson¹² in 1939 announced that triphenyl chorethylene had estrogenic activity. They recommended that the dose of this compound for adults be 200 mg daily. The duration of action was approximately that of diethylstilbestrol, and no nausea or other side reactions were observed.

SYNTHESIS OF OCTOFOLLIN

Blanchard¹³ studied the response of rats to a new synthetic estrogen 2-4-di-(*para*hydroxyphenyl)-3-ethyl hexane, later named octofollin. This compound is not related to stilbestrol. He found that it produced responses in rats similar to those elicited by the natural estrogens except that it was highly active when administered by mouth. Certain natural and synthetic estrogens when given parenterally or orally in large repeated doses will produce hypoplasia of the bone marrow of dogs.¹⁴ Stebbins and Blanchard¹⁵ observed hypoplasia of the bone marrow of rats receiving either a natural estrogen diethylstilbestrol or octofollin. The incidence and degree of the hypoplasia of the bone marrow was not as great with octofollin as it was with either of the two other estrogens.

Freed, Eism and Greenhill¹⁶ found satisfactory therapeutic response to this new synthetic estrogen in patients receiving 10 to 25 mg daily. Results were judged chiefly by the relief of hot flashes. They reported nausea in only 3 of a small series of cases.

In 1940² and again in 1941⁴ two of us summarized our studies with diethylstilbestrol in which the subjective, objective and possible toxic responses of patients to the medication were investigated. We report here a similar study with the new synthetic estrogen octofollin.¹⁷

CLINICAL MATERIAL AND METHODS

During the past fourteen months we have treated over 60 persons having estrogen deficiency with octofollin. Forty-four case studies are analyzed in this report, since the attendance of the remaining patients at the clinic was irregular. Of the 44 women, 30 suffered from symptoms of spontaneous menopause, 11 from artificial menopause following operation, and 3 from primary hypogonadism. No patient was treated who did not complain of severe symptoms of vasomotor instability.

The subjective symptoms of each patient were analyzed as carefully as possible and recorded in specially prepared charts prior to and during the admin-

¹⁷ The octofollin was supplied by the Research Laboratories of Schieffelin & Company, New York.

istration of octofollin. Vaginal smears were taken before medication was given and at frequent intervals during the course of therapy.

In the early part of the studies each patient was given 0.5, 1.0 or 2.0 mg daily of the estrogenic substance by mouth for six to eight weeks, however, these doses gave little therapeutic effect. Therefore the doses were gradually increased to 5 mg or more daily. A few

Total	18	22	12	23

of the patients with severe symptoms required from 10 to 15 mg daily to obtain relief. Continuous therapy was employed in 26 cases. Of the 26 patients receiving continuous medication, 5 received the estrogen from one to three months, eight between three and six months, five from six to nine months, and 8 for nine months or longer.

Eighteen patients were given interrupted treatment. The patients at first received 1 mg daily for fourteen days, then the octofollin was omitted for two weeks. The next month the dose was increased to 2 mg daily for the two week period. The patients obtained slight or no relief from these doses. The following month the dose was increased to 5 mg, then to 10 and 15 mg in the succeeding months. Of the 18 patients given interrupted medication, 7 received this type of treatment for five months and 11 for seven months or more.

For comparison with the studies on diethylstilbestrol reported in 1941, hepatic function tests were done on 9 patients receiving large doses of octofollin. The two tests employed were bromsulphalein excretion and hippuric acid synthesis.

In 26 cases complete counts of the formed elements of the peripheral blood (excluding platelets) were performed prior to and during the administration of octofollin. Repeated urine examinations were done in all cases.

RESULTS

1 Subjective Effects—Good relief of symptoms of vasomotor instability was observed in 23 of the total of 44 patients receiving either continuous or interrupted treatment. Fair relief was obtained in 10 patients, poor in 4 and no improvement in 1. Hot flushes were eliminated or diminished greatly in 15, and headaches were relieved in 11 patients in whom they had been prominent complaints. Of 26 patients, nervousness was diminished in 16 and fatigability in 14.

In table 1 are presented the subjective effects of four different levels of dosage of octofollin on the 26 patients given continuous treatment. The table shows that the majority of the patients received little or no benefit with doses of 1 to 4 mg daily. Only 2 of 22 patients were fairly satisfactorily relieved of symptoms with 2 mg daily. Among 12 patients receiving 4 mg daily, symptoms were greatly diminished in 3, while in 7 only slight relief occurred, and in 2 there appeared to be no change

With 5 mg daily, 5 patients obtained slight relief, 6 fair, 8 good and 4 excellent alleviation of symptoms. When 1 patient was given 6 mg and another 10 mg daily, each one obtained complete relief of symptoms of the menopause.

The subjective effects of interrupted therapy on 18 patients are presented in table 2. There was little or no effect from either 1 or 2 mg daily, given two weeks out of four. With 5 mg daily, 6 patients obtained good relief of symptoms, 4 fair and 8 poor, while with 10 mg for the two week period there was excellent relief of symptoms in 4 patients, good in 7 and fair in 7. When the daily dose was increased to 15 mg, the same 4 patients obtained excellent results, 7 good and 7 fair.

From these results it would seem that from 5 to 10 mg of octofollin daily is required in the majority of cases to relieve satisfactorily the symptoms of vasomotor instability occurring in the menopause. This conclusion is at variance with the observations of Freed, Eisin and Greenhill,¹⁶ who found that the satisfactory daily dose of octofollin was from 1.0 to 2.5 mg. Taylor and Thompson,¹⁸ however, had to give from 30 to 50 mg by mouth daily to produce the same estrogenic effect as 1 mg daily of diethylstilbestrol. Nausea, vomiting, heartburn and leg cramps were much less frequently observed than with diethylstilbestrol but were noted in some instances in their series of patients receiving octofollin.

We observed few untoward reactions. Three women receiving 10 mg doses of octofollin over a long period complained of mild discomfort in the lower part of the abdomen. Five patients given 10 to 15 mg daily observed an increase in the white seromucoid vaginal discharge. This occurs much more frequently with diethylstilbestrol.

Nausea did not occur in any of the 44 women we treated, even with doses as large as 10 to 20 mg every twenty-four hours. Greenhill,¹⁶ however, reported nausea recently in 2 of 18 patients receiving 5 mg daily of octofollin. When the dose was reduced to 2 mg daily he found that the incidence of nausea of 39 patients decreased to 2.6 per cent.

A number of our patients had received diethylstilbestrol two to three months prior to octofollin treatment,

TABLE 2—Subjective Responses of Eighteen Women Receiving Interrupted Treatment with Octofollin

Excellent				4	4

and many of the patients felt that diethylstilbestrol had produced greater improvement in strength and energy than did the new synthetic estrogen.

2 Objective Effects—We employed the vaginal smear as a simple objective means to measure estrogenic activity, although we believe that the subjective results are clinically more important than the exact degree of estrogenic response determined by any objective test. Among 18 women obtaining some relief of symptom

18 Taylor, S. G., III, and Thompson, W. O. Experiences with a New Synthetic Estrogen for Oral Administration, *Endocrinology* 27: 20, 1942 (June).

on continuous therapy with 5 mg daily of octotollin for six to eight weeks there was an increase in the estrous activity of the vaginal smear in 3 from an inactive type or a 1 plus to a 2 plus or more while the cellular changes in the vaginal smears of 6 patients showed a rise of only 1 plus and in 9 there was no change. Sixteen women of the total group of 26 patients on continuous therapy showed no discernible change in their vaginal smears, however 4 of these patients had 3 plus smears at the beginning of the experiment. Thus the administration of the estrogenic substance did not produce any significant change in the vaginal smears in approximately 50 per cent of the 26 women treated with this method and in no instance was a complete (or 4 plus) vaginal smear response produced.

Of the 18 patients given interrupted treatment, 12 had negative (inactive) vaginal smears 4 showed 1 plus and 2 showed 2 plus smears before octotollin was given. After five to seven months of therapy beginning with 10 then 20, 50, 10 and eventually reaching 15 mg daily doses for a two week period each month, 8 women had 1 plus vaginal smears, 7 had 2 plus and 3 had 3 plus.

Since in a number of the women experiencing satisfactory alleviation of their menopausal symptoms there was little if any change in the cells in the vaginal smear after prolonged therapy, it was impossible to correlate symptomatic relief with objective results.

Several patients given 10 to 15 mg of octotollin daily noted some tenderness of the breasts and an increase in pigmentation of the areolae. We have observed similar changes more frequently in patients receiving 10 mg daily of diethylstilbestrol.

Uterine bleeding was produced in 3 of the 18 women given interrupted treatment. It usually occurred seven to ten days after the discontinuance of daily doses of 5 to 15 mg of octotollin. It did not appear when smaller doses were employed.

STUDIES OF TOXICITY

1 *Hepatic Function Studies*—Hepatic function was studied both by hippuric acid synthesis and by the bromsulphalein excretion of 8 women given an average of 4 to 5 mg daily of octotollin for five months. The tests were performed in all of the cases before any treatment was given and repeated after a period of five months of therapy. In 7 cases the results of the hippuric acid synthesis tests were within normal limits both before and after treatment. The values for this test in 1 case were below the level of normal both before and after therapy. The results of the bromsulphalein excretion tests on each of the 8 patients were within normal limits both before and after treatment. There was therefore no significant change in hepatic function attributable to the administration of octotollin. We¹⁹ have previously shown that neither diethylstilbestrol nor estradiol in the doses used in the treatment of the menopause produce any demonstrable change in the function of the liver in human beings.

2 *Blood Studies*—During octotollin therapy no abnormality in the number of erythrocytes or leukocytes among 26 patients studied was observed while the total grams of hemoglobin and the differential counts of the leukocytes remained within the range of

normal values. The only bleeding tendency that occurred was the uterine bleeding produced in 3 women by the withdrawal of the estrogenic substance.

3 *Urine Studies*—Repeated examinations of the urine of 38 patients showed no changes that could be attributed to the medication.

ANIMAL EXPERIMENT

For comparison with the studies made by one of us²⁰ on the changes in the bone marrow of dogs following the administration of estradiol or diethylstilbestrol, an experiment was done to determine the effect on the bone marrow of dogs of intramuscular injections of octotollin.

Studies were performed on 2 mature healthy male dogs, weighing 11.5 and 14.5 Kg. As in the previous experiments the animals were kept for a conditioning period of three weeks prior to injection of the octotollin. Red and white cell and platelet counts were done on the peripheral blood two to three times a week during the control and experimental periods.

Each dog was given a daily intramuscular injection of 5 mg of octotollin in oil for fifty days. There occurred a slight rise in the number of leukocytes in the peripheral blood of each animal at about the eighteenth to the twenty-fifth day of treatment. We did not observe the simultaneous decrease in the number of thrombocytes which occurs with much smaller doses of estradiol or of diethylstilbestrol. The amount of octotollin injected was increased to 15 mg daily for fourteen days, and there occurred a fall in the number of thrombocytes in the peripheral blood of the smaller dog. Each animal was then given 20 mg daily for sixteen days. At the end of this period there was a definite reduction in the number of thrombocytes and leukocytes in the circulating blood of the smaller dog. A slight thrombocytopenia was demonstrated in the peripheral blood of the larger animal. An autopsy was done on each dog at the end of eighty days of treatment, and a mild hypoplasia of the bone marrow of the smaller animal was found. There was no significant change from normal in the bone marrow of the other animal.

Each dog received approximately 780 mg of octotollin in sesame oil in eighty days but pronounced changes were seen in the peripheral blood of only 1 animal. A total of 210 mg of diethylstilbestrol dipropionate in olive oil injected during twenty-one days, or an estrogenically equivalent dose of alpha estradiol in sesame oil injected during thirteen days has been shown to produce leukocytosis, thrombocytopenia and death in dogs²⁰. Our observations would indicate that diethylstilbestrol and estradiol are by this test, much more potent than octotollin.

SUMMARY

The majority of 44 women obtained relief of the vasomotor symptoms of hypogonadism when given octotollin by mouth in doses of 5 to 15 mg daily. Of 26 patients given continuous treatment 15 (58 per cent) obtained good relief of symptoms, 6 (21 per cent) fair, 4 (15 per cent) poor and 1 (4 per cent) no relief. Satisfactory alleviation of symptoms was secured in 11 of the 18 patients given interrupted therapy. The

19. Caicedo, Dante, Bierbaum, Olga, Hevner, F. B., and MacIntyre, C. M. Comparative Studies of the Effect of Estradiol and Stilbestrol on the Blood, Liver and Bone Marrow. *Endocrinology* 29: 20-22 (Sept. 1941).

19. MacBride, Freedman, Loeffel and Castrodale. MacBride, Castrodale, Loeffel and Freedman.

required larger daily doses for the two week period each month than the patients on continuous treatment. Among the 18 patients receiving 15 mg daily for two weeks each month 11 (61 per cent) obtained good subjective response while 7 (39 per cent) obtained only a fair effect.

Nausea did not occur in any of the patients studied. Three patients (8 per cent) had discomfort in the pelvis, and several women noted tenderness of the breasts and increased pigmentation of the areolae when given 10 to 15 mg daily. Vaginal bleeding occurred after interruption of treatment in 3 of 18 cases.

The majority of our patients required from 5 to 10 mg daily for adequate relief of symptoms. In the series given interrupted treatment the average daily dose for the two week period was 10 to 15 mg.

Objective studies gave less definite evidence of estrogenic activity. Only 9 of 26 women (35 per cent) receiving 5 to 10 mg daily had any change in the vaginal smears, and not one of these developed a complete estrous response. A slight to moderate change in the cellular type of the vaginal smears of each of the 18 patients on interrupted treatment was observed. Twelve of these patients had inactive vaginal smears before octofollin was given. In our experience 1 mg daily of diethylstilbestrol produces in the average case complete response in the vaginal smear in twenty-one days. Our observations indicate that, per milligram, diethylstilbestrol is at least five to ten times as potent when given orally as octofollin.

The very low incidence of side reactions particularly of nausea is of clinical importance. Disadvantages of octofollin are that comparatively large doses are required and that it is more expensive per milligram than diethylstilbestrol. It is however less expensive per clinically effective unit than oral preparations of "natural" estrogens.

Liver function tests, blood studies and urine examinations showed no toxic effects of the new synthetic substance. Octofollin in the doses used in this experiment is apparently a safe therapeutic estrogen.

CONCLUSIONS

- 1 The new synthetic estrogen octofollin is effective in treatment of hypogonadal symptoms in women.
- 2 It appears to be relatively nontoxic, since nausea did not occur in this series of 44 patients, and no other toxic manifestations were observed.
- 3 The effective oral dose is from 5 to 10 mg daily when continuous treatment is used or from 10 to 15 mg daily for interrupted treatment.

Infantile Paralysis—The normal and usual method of travel of the virus throughout the body is reported to be by the pathways provided by the nerves. This is a neurotrophic or neuronotrophic virus. It leaves no demonstrable histologic change as it travels over or through the nerve fibers, yet its spread by way of neurons is dependent on healthy normal fibers and nerve cells. For example, it cannot progress in nerve tissue that has not fully regenerated after traumatic changes. The rate of the progression of the virus in peripheral nerves to the central nervous system has been calculated by Howe and Bodian to be at the rate of 24 mm per hour in the experimental animal. Such travel occurred in both the motor and the sensory fibers.—Gudakunst, Don W. *New Developments in Infantile Paralysis*, *New York State J Med* 43 1514 (Aug 15) 1943.

MENINGOCOCCIC MENINGITIS AND SEPTICEMIA

REPORT OF OUTBREAK IN FOURTH SERVICE
COMMAND DURING WINTER AND
SPRING OF 1942-1943

COLONEL HENRY M THOMAS JR
Medical Consultant, Fourth Service Command,
Army of the United States

Cerebrospinal meningitis has occurred wherever large numbers of troops have been brought together. During and after World War I there were in the United States Army a little less than 6,000 cases in the course of thirty-three months.¹ The over all mortality for that series of cases was 39 per cent. Following the war the cases in the civilian population of the United States continued for ten years at a high rate, but by 1930 the incidence of cases had fallen to its usual prewar level.² For the years 1939, 1940 and 1941 slightly less than 2,000 civilian cases per year were reported for the whole country. The year 1942, however, showed an increase with 3,400 cases during the first eleven months.

In the Fourth Service Command sporadic cases of meningitis occurred during the years 1941 and 1942.

Relation of weekly incidence of meningococcic meningitis to that of common diseases of the upper respiratory tract as observed in 1942-1943 in the Fourth Service Command. Each figure at the left or the right represents the number of cases per thousand annually.

The case rate per thousand troops began to increase in December 1942 and what might be termed a clearcut outbreak was well on its way by the first of January. At this time simultaneous outbreaks occurred at an army station in North Carolina, at one in South Carolina and at one in Alabama, and two weeks later a camp a few miles from the first one in Alabama reported an outbreak. A large preponderance of new troops were on duty at these posts during this time.

The chief of the Medical Branch, Headquarters Fourth Service Command, has encouraged and expedited all the work mentioned in this report. This article in brief form was read at the regional meeting of the American College of Physicians, New Orleans, April 16, 1943. The statistics have been revised to include April, May and June 1943. Members of some fifty station hospital staffs have contributed observations and studies on cases occurring in their respective camps. A majority of the cases have come from the services of Lieut. Col. W. B. Daniel, J. E. Knighton, O. B. Mayer, Louis Ochs Jr. and A. W. Wall. Majors M. R. Buchman, R. W. Houser, A. C. McCarty and A. J. Sullivan, and Capt. W. B. Malcolm. Treatment has been entirely in their control and has followed with minor modifications the recommendations contained in Surgeon General's Official Circular Letter No. 1, and memoranda from the Chief of the Medical Branch, Headquarters Fourth Service Command. This article does not completely express the views of the medical staff of any one station hospital but is the result of a study of their work supplemented by personal clinical and epidemic observation of the cases as they occurred at many of the posts.

1 Simmons, James S. and Michie Henry C. *Cerebrospinal Meningitis*, chapter IV in *The Medical Department of the United States Army in the World War* U. S. Gov. Printing Office 9 20, 1929.

2 Mitchell Roscoe I. *Epidemic Meningitis*, *J. Maine M. A.* (March) 1943.

In three of these four camps no 2 patients came from the same company or barracks and the outbreak presented the epidemiologic appearance of being merely an increase in sporadic cases. In the fourth camp two companies had 6 and 8 cases respectively in addition to the sporadic cases elsewhere on the post. The pattern of outbreaks of meningitis is clearcut and may be stated as follows. Simultaneously at distant points an increase in sporadic cases occurred reaching a peak in several months and declining after several more months.

In this outbreak as in previous ones the increase in case rate followed a pronounced increase in infections of the respiratory tract. This is well shown in the accompanying chart. It is to be noted that the rate of meningitis is plotted on a scale one twenty-fifth of that of diseases of the upper respiratory tract.

During World War I definite advances were made in the epidemiology of meningococcic infections. It was found that there is constantly in nonepidemic periods a carrier rate between 1 and 2 per cent. During epidemics, however, this carrier rate rises to the neighborhood of 30 per cent or higher depending on local circumstances. Since the last war these facts have been corroborated frequently and it has further been learned that if a high carrier rate is to be significant the organism involved must be group I meningococcus since during epidemics 90 per cent or more of all cases are caused by this organism.⁴

The facts described, namely increase in sporadic cases and localized epidemics following a wave of infections of the upper respiratory tract associated with a great increase in the meningococcus carrier rate among large groups of troops, provide evidence for a concept of the epidemiologic nature of meningococcic outbreaks. Among the new troops brought into an army post there is a rate of at least 1 to 2 per cent meningococcus carriers. If their arrival at camp occurs during the months when diseases of the upper respiratory tract are prevalent an extremely high rate of such diseases soon develops among the new troops and includes the carriers. The coughing and sneezing distribute not only the virus responsible for the diseases of the upper respiratory tract but also the meningococci introduced by the carriers. In this way the carrier rate builds up rapidly. In susceptible persons during periods of fatigue and exposure the carrier state may progress into one of the clinical forms of meningococcic infection.

These facts have been carefully considered by various physicians interested in lowering the case rate of meningitis and recommendations have been made⁶ which if possible to be carried out would undoubtedly greatly lower the case incidence. For instance Glover⁷ in 1918 showed that avoidance of crowding by adequate spacing of cots reduced the carrier rate from 29 to 4 per cent. Others have recommended in addition avoiding exposure fatigue and too rapid inoculation for typhoid and other diseases. However, all of these rules must be broken when it becomes necessary to build a huge army with the utmost speed. Under these conditions it is impossible to avoid all or even one of these conditions. It is fortunate therefore, that modern methods of treatment of the patients and more

recently prophylactic treatment have reached such a degree of excellence that the problem is in a fair way toward being solved by chemotherapy.

STATISTICAL REVIEW

The present study comprises the cases of meningococcic infection which occurred in troops of the United States Army throughout the seven Southeastern states during the months of December 1942 and January, February, March, April, May and June 1943, the total

number of cases for this period being 1935. Table 1 shows the cases by months and it will be seen that the incidence of cases has decreased (table 2).

Table 3 shows the distribution of deaths from meningitis and septicemia in new and in seasoned troops. An arbitrary period of three months' service was taken to define new from seasoned troops. It will be seen that slightly more than two thirds of the total cases developed among new troops (table 4). It must be remembered however that the final significance of this fact can be determined only when the numbers of new and old troops can be compared and to many reasons this information is not yet available. Ordinarily

cases showing a clearcut increase in cells in the spinal fluid would be classified as cases of meningitis but the fatal cases have been divided according to the principal cause of death. If the count in the spinal fluid had not reached more than 400 cells before death the patient was classified as dying of meningococcic septicemia, although it is realized that this may be a distinction without a difference. Nearly half the deaths (23 of 51 cases coming to necropsy) occurred in cases in which meningitis had not developed to a point where the cellular response in the spinal fluid was impressive. That response is interpreted as an index of severity of infection, and this is borne out by the finding of hemorrhages in the adrenals in 16 of these cases.

At several posts Major John I. Pontas obtained information on the proportion of cases coming from urban or rural districts and found that there was no difference. This suggests that during nonepidemic periods urban dwellers are no more exposed to group I meningococcus than rural dwellers.

Mortality.—At first glance (table 1) there seems to be some discrepancy between the general mortality and the higher mortality during the months of December

and January. If this is broken down into individual weeks (table 2) it will be seen that the mortality for the 40 cases during the week ended January 1 was 20 per cent. This unusual occurrence gave rise to immediate activity in the Fourth Service Command Headquarters and notices were sent out to all surgeons of the Fourth Service Command warning them about the presence of meningitis and meningococcic septicemia and advising prompt therapeutic measures. In retrospect it seems that the high mortality for that one week was caused by a combination of circumstances, since the virulence of the disease and the number of new troops have remained essentially the same. The deaths occurred largely at new posts, where the medical personnel was new to military medicine. In addition to this, sodium sulfadiazine for intravenous use was not available at most of the hospitals at that time. Some of the patients were admitted in the evening and were seen only by the officer of the day, who in many instances was a member of one of the surgical branches of the staff and therefore not thoroughly familiar with cases of meningococcic septicemia. Finally, and perhaps most important, few of the reserve officers on duty in the medical corps had had previous experience with cases of meningitis, and most of them had never seen a case of meningococcic septicemia.

Active interest was aroused in the entire subject of meningococcic infections. Local scientific meetings

were held, and discussions in regard to therapeutic measures were engaged in. Improved cultural technique for isolating the meningococcus was prepared and distributed to laboratory officers at station hospitals by the Fourth Service Command Laboratory. This interest spread also throughout the unit medical officers with troops so that within ten days all medical officers of the command were on the lookout for cases, and directions prepared for the treatment of patients brought into hospitals during the night were posted by the chiefs of the medical services of the various station hospitals. At station hospitals where cases were numerous a member of the contagious disease section of the medical service was placed on night duty, so that all details of diagnosis and treatment were carried out promptly and accurately. In addition to this the nurses on night duty throughout the hospital were alerted to the possibility of patients developing signs of coma or exhibiting cutaneous rashes. Whether the additional therapeutic measures which were used and are described later as adjuncts in the section on treatment added anything to the reduction in mortality is not perfectly clear, but this remains as a distinct possibility. It seems probable that all members of the medical corps on duty in the zone of interior during the past few months will continue to be on the watch for cases of meningococcic infection and will be familiar with proper treatment so that it is safe to prophesy that the mortality rate for the remainder of this war will be held to a low level.

The mortality figures for this series include a number of patients who died in the hospital before their condition was recognized and who received no specific therapy. In addition one patient is included who died before he was admitted to a hospital. These facts suggest that a perfect system of early diagnosis leading to prompt treatment would reduce the mortality still further. That this has already been attained to a high degree may be seen from the statement that at one post while 108 patients were being treated with a mortality of under 3 per cent there were in the county 8 civilians with the disease, 4 of whom died—a mortality of 50 per cent.

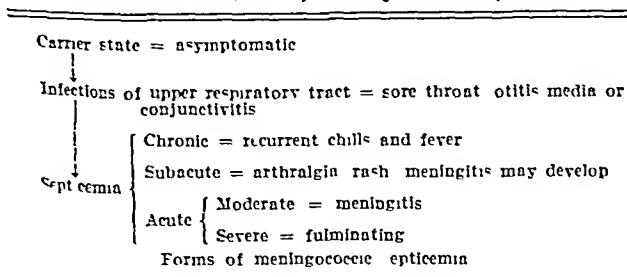

The report of meningitis throughout the state of Maine for the year 1942 gives a mortality of "something over 14 per cent, which is very low."² There are eight rather large posts in the Fourth Service Command where an aggregate of 161 patients with meningococcic infection were treated without a death. There were 49 other patients scattered throughout twenty-one small posts without a death. These facts are brought out to show merely that even in a single command mortality rates differ from post to post, depending on the number of cases of fulminating infection that are encountered. Eight patients with meningitis received no specific treatment, and in 8 others treatment was started so late as to be almost hopeless. With regard to the 17 remaining patients, retrospective improvements in therapeutic technique are possible. The improvements fall into all the various aspects of modern therapeutic procedures such as proper administration of sulfonamide compounds, control of fluid balance, control of electrolyte balance, control of intracranial pressure, avoidance of distention of the bladder, sedation and nourishment. Fulminating infection may require certain adjunctive measures as well. In no large hospitals one or two medical officers have become expert in these procedures and have been given complete responsibility for the entire treatment of

patients with meningococcic infection. This specialization has produced noticeable improvement in methods and results. Any comparison of army mortality with civilian mortality requires consideration of various factors but the excellence of army practice remains a matter for justifiable satisfaction.

CLINICAL MANIFESTATIONS OF MENINGOCOCCIC INFECTION

During the course of the years 1941 and 1942 sporadic cases of meningococcic infection were encountered in the army throughout the entire country. The infection consistently conformed to the usual pattern of cerebro-spinal meningitis with a history of chilliness, frequently of chills, sore throat, headache and occasionally a gastrointestinal upset. Examination of the patients revealed fever, leukocytosis, drowsiness, stiff neck and often petechial lesions of the skin and the spinal fluid contained between 1,000 and 20,000 cells, predominantly polymorphonuclears. Blood cultures were positive in some cases and the spinal fluid usually contained visible intracellular or extracellular gram-negative organisms although occasionally these were demonstrable only by culture. Spinal puncture was performed once for diagnostic purposes and occasionally

A Schematic Diagram of Meningococcic Infections

a second time to prove cure or to differentiate drug fever from persistence of meningitis. In a few cases relief of excessive intracranial pressure by spinal tap quieted extreme restlessness for some hours, and in 1 case it was performed with benefit four times in the course of twenty-four hours. In another case extreme Biot breathing was relieved by several taps during the early hours of the disease and one or more patients might in retrospect have been saved by this procedure. Otherwise no useful purpose was gained by repeated spinal taps. In 2 cases death seems certainly to have been precipitated by the production of a pressure cone causing sudden unexpected death.

During December a few cases of meningococcic septicemia made their appearance and the number rapidly increased during January, so that during the last two weeks in January there was a total of 61 cases. It seems fairly certain now that every clinical meningococcic infection with the possible exception of a variety of infection of the upper respiratory tract consists at some stage of an invasion of the blood stream by the causative organism. In most instances the organism localizes in the meninges producing clinical meningitis but in certain cases this does not eventuate. Meningococcic septicemia can be divided into acute, subacute and chronic forms as shown in the accompanying outline.

Acute Forms—Acute meningococcic septicemia early in its course presents a picture similar to grip or streptococcic sore throat with headache, chilliness or chills,

backache and muscle ache. Soon this picture is apt to change, however, and restlessness and drowsiness supervene, often progressing rapidly to coma. Frequently the patients are brought into the hospital in a comatose state. The most fulminating type of infection ends fatally in the course of a few hours. One patient at a Southern camp was drilling at 10 a.m. when he reported feeling bad and at 1 p.m. he died. This same fulminating type of disease has been observed throughout the command in about 12 instances. In 6 of these cases organisms were seen in the peripheral blood smear.

Many of the patients with fulminating infection were admitted to the hospital in a state of shock with blood pressure between 50 and 80 mm. of mercury. Frequently such patients had evidence of widespread hemorrhages throughout the skin and mucous membranes. Usually the spinal fluid of patients with this type showed few if any cells. Many of the patients were thought to have had hemorrhages into the adrenal glands (Waterhouse-Friderichsen syndrome). Among patients with fatal infection there were 26 who died during the period of acute septicemia before meningitis developed. Autopsy was performed on 23 who died of septicemia and hemorrhages into the adrenals were present in 17. In an additional patient edema and congestion of the adrenal glands were noted.⁸ Great efforts have been made to evolve a form of treatment which would enable such patients to be cured and this regimen includes the various adjunct measures described in the paragraph dealing with treatment. Bacteriologic correlation has not been worked out but all three groups of meningococci are represented in this small series of 14 fatal cases. It will be recalled that in children organisms other than meningococci are held to be responsible for fulminating septicemia associated with hemorrhage into the adrenal glands. The only organism other than the meningococcus which has been encountered in such cases in this group is *Neisseria catarrhalis*, which in 1 fatal case was the only organism recovered. Its exact significance is unknown but it was thought probable that the meningococcus had been present but was not demonstrated in the cultures.

Patients with slightly less severe septicemia lapse into coma from which they are aroused only by rapid and heroic treatment. They may show petechial or ecchymotic cutaneous lesions which in some develop into huge purpuric areas. These lesions of the skin are apt to develop rapidly, and on many occasions medical officers have noted that new lesions developed under their observation while they were performing spinal tap. An entirely different cutaneous eruption has been observed in many cases of both chronic and acute septicemia. This has been described in the British literature and in the *Lancet* in 1941. Majors Dickson and McKinnon and Captains Wagner and McGillivray⁹ gave an excellent account of it as it occurred in a Canadian army general hospital. The lesions appear in groups of a few or dozens and most commonly on the limbs or trunk. They are round, well defined, maculopapular, often tender, 5 to 35 mm. in diameter, usually with dark red or purple centers. The pink area fades on pressure but the dark central spot does not. These lesions are apt to become more hemorrhagic in the

⁸ In 3 fatal cases of meningitis hemorrhages into the adrenal glands were discovered at necropsy.

⁹ Dickson, R. C., McKinnon, A. E., Wagner, D., and McGillivray, A. B. Meningococcal Infection. *Lancet* 2: 631-634 (Nov. 2) 1941.

course of a day or two, and as the patient improves they fade in two to four days, leaving small pigmented areas. Excellent descriptions of this form of eruption have been made by several medical officers in the Fourth Service Command.¹⁰ At posts where many such cases have been seen this rash is recognized as characteristic enough to establish the diagnosis of meningococcic septicemia. The Canadian authors emphasized the fact that localized pain or tenderness of muscles is a symptom which differentiates meningococcic septicemia from other forms of acute infection. In many of our army posts it has been noticed that acutely inflamed joints or merely exquisitely painful joints have been complained of in many instances.

Differing from the acute severe and the acute fulminating infections are others which can be called acute mild meningococcic septicemia. The onset is like that already described but the patients do not seem to be particularly ill; they respond immediately to treatment with sulfonamide compounds and are well in a day or two. In fact 3 patients, each having a blood culture positive for meningococci of group I, recovered spontaneously without drug or serum therapy before the culture was known to be positive. Many similar patients with characteristic cutaneous eruptions but with negative blood cultures are believed to have a meningococcic infection falling in this mild group but have not been included in the statistical study.

Chronic Forms—Chronic meningococcic septicemia presents a picture which frequently may be mistaken for malaria, either tertian or quartan or some form of relapsing fever. The patient suffers from episodes of chilliness, fatigue, headache, general malaise, fever, leukocytosis and usually one or the other of the cutaneous lesions described in the foregoing paragraphs. The disease may continue on its relapsing course for several months unless the patient is treated, although spontaneous recovery occasionally occurs. The diagnosis is frequently aided by a special technic blood culture which is most apt to yield organisms if taken while the patient is having a chill.

Subacute Forms—Subacute meningococcic septicemia simulates rheumatoid arthritis or acute rheumatic fever and is frequently associated with fluid in the knee joints. The patients occasionally improve under nonspecific symptomatic treatment but more often they develop in a week or two signs and symptoms of meningitis, at which time the diagnosis becomes apparent. Routine cultures from the joint fluid sometimes provide the diagnosis, and in a few cases culture of the joint fluid has been positive after several days of chemotherapy. In other instances the characteristic cutaneous eruption gives rise to the correct diagnosis.

In epidemiologic circles the carrier state is considered as a subclinical, asymptomatic form of meningococcic infection. In addition to this it is thought by many that nasopharyngitis can be produced by meningococci and a number of cases of conjunctivitis (7 cases have been confirmed bacteriologically at one station hospital) and otitis media have been shown to be caused by this organism.

COMPLICATIONS

In patients receiving early chemotherapy complications are extremely rare. Statistics are not yet available, but a personal survey of this service command

has left me with a recollection of a few patients with deafness (3 such patients have been discharged from the army on account of residual deafness), a few with diplopia who recovered, and a few with stiff joints, who recovered completely or partially. One patient was left with a persistent paralysis of the right serratus maximus muscle. Hematuria is seen frequently before any therapy is started but no nephritis has been seen during convalescence. Retention of urine with distention of the bladder is frequently seen in comatose patients, and in these catheterization may reduce restlessness. Accompanying encephalitis has produced coma early and a few of the patients with the fulminating form of septicemia have been brought to the hospital following the initial symptom of convulsions. Several others have died before the true nature of the condition was discovered. Bronchopneumonia occurred occasionally and was seen at necropsy. In most of the patients who recovered from meningitis cure was complete, although a few soldiers continued to complain of recurrent headache for some weeks or months and psychoneurosis has been noticed in some.

Four patients have had large sloughs involving the skin and subcutaneous area in the location of confluent purpuric areas. Two of these required skin grafting.

On the whole, complications have been conspicuous by their rarity.

POSTMORTEM OBSERVATIONS

Final reports of the postmortem examinations have not been received. Several facts stand out from the gross examinations. Usually in septicemia there were widespread petechial hemorrhages in the meninges and many other organs and often also gross hemorrhages into the adrenal glands. Hemorrhage was associated with, or secondary to, localized thrombosis of the vessels in some cases. In many of the thoroughly treated patients with meningitis clearcut evidence of the exact cause of death was lacking. One finds such statements as "In summary, the remarkable thing about this autopsy was the absence of positive findings." In cases in which there was a high cell count in the spinal fluid during life—sometimes as high as 19,000 polymorphonuclears—as well as visible and recoverable meningococci, little evidence of meningitis was apparent in the gross specimens at postmortem examination. The meningitis might be said to have been practically cured, but irreversible effects of sepsis seem to have caused death. In every fatal case several possible causes of death presented themselves. Some patients seem to have died of respiratory failure either from toxic effect on the respiratory center or from increased intracranial pressure with Biot breathing. Patients who die of septicemia die in shock, and most of them also develop acute pulmonary edema. This pulmonary edema occurs in untreated as well as treated patients and may be part of the picture of shock or it may be produced by the acute myocarditis seen in some cases. Liberal quantities of fluids injected intravenously and large doses of sulfonamide compounds, which are capable of producing myocardial and renal lesions, may be considered also as contributing causes, but I have seen no worth while evidence that can incriminate these therapeutic agents. Of 64 fatal cases 51 were examined post mortem. In 2 cases crystals were present in the renal substance although anuria had not developed. In a number of cases tubular lesions were present and many had been produced by sulfadiazine. It is also to be remembered that nephritis is a complication.¹¹

¹⁰ In the older American writings these lesions are spoken of as resembling rose spots or erythema nodosum.¹¹

¹¹ Herrick, W. W. Text Book of Medicine by American Authors, edited by R. L. Cecil, Philadelphia, W. B. Saunders Company, 1942.

meningococcic disease. Further light on this subject is hoped for from careful clinical and pathologic study of fatal cases. Correlation of the types of organisms with the different varieties of fatal cases is being undertaken. From present information 13 fatal cases of meningitis yielded group I *Neisseria intracellularis*, 2 group II and 1 *N. catarrhalis* while from 12 cases of septicemia there were 7 with group I, 2 with group II, 2 with group II A and 1 with *N. catarrhalis* (table 5).

BACTERIOLOGY

Studies of organisms encountered in the outbreak have yielded the usual percentage for each of the various groups. The organism most often recovered is group I meningococcus. Group II meningococcus has been found in only 2 or 3 cases. Group II A was found in about one tenth of the cases. These findings are similar to those reported in other outbreaks.

In more than half of the instances in which the diagnosis of meningococcic meningitis was made there was bacteriologic confirmation in the laboratories of the various station hospitals. A large number of the patients with positive spinal fluid cultures also had positive blood cultures. The numbers of positive cultures reported are directly related to the grades of efficiency of the individual laboratory units and in view of the wide distribution of the reported material the average level of laboratory diagnoses appears high. During an epi-

TABLE 5—Thirty Three Fatal Cases Divided According to Type of Organism

Meningitis	16	1	2	0
Septicemia	8	1	4	1

demic there may be more clinical diagnoses unconfirmed by bacteriologic studies than would be permissible in a period of sporadic meningitis. Several specimens of spinal fluid containing only from one to five cells have yielded meningococci on culture. In the case of one of these the fluid was tapped six hours later and then contained 4,000 pus cells.

TREATMENT

The amazing reduction in mortality from 39 per cent in the last war¹ to less than 3.5 per cent in the present war is due entirely to chemotherapy.¹² It is true that the most desperately ill patients may require additional therapeutic measures but for over 95 per cent of all patients chemotherapy properly administered is the only specific form of treatment necessary.

Of the various sulfonamide compounds sulfadiazine has up to the present proved to be the most satisfactory in the treatment of meningococcic infections. It is more efficacious than sulfanilamide and with one important exception it is much less toxic than sulapyridine and sulfathiazole. The sodium salt is available for intravenous treatment and can be administered in 5 per cent concentration in distilled water or in 1,000 cc of isotonic solution of sodium chloride. If all patients could be given a diagnosis and treated at the onset of the first symptom, it is my firm belief that the mortality would be reduced to zero. However the disease is often masked by the absence of pathognomonic symptoms and by the simultaneous occurrence of many infections

of the upper respiratory tract presenting similar symptoms. This leads inevitably to loss of time in treatment in a few cases. In other cases the infection is so virulent that the patient dies before treatment can be given or before treatment has an opportunity to stem the tide of infection.

Treatment of carriers with sulfonamide compounds has been reported from England,¹³ Australia and various small groups in the United States.¹⁴ Fairbrother¹³ found only one carrier in a group of 139 patients in a British military hospital who were undergoing treatment for another disease with sulapyridine (total dose about 22 Gm.) while a control group contained 22 per cent carriers. He then treated 13 known carriers with 10 Gm. in three days and eliminated meningococci from the nasopharynx in all 13. Mueller¹⁴ during the course of a rather sharp outbreak of type I infections in New England treated 200 persons, of whom between 60 and 70 per cent were carriers and was unable to recover the organisms from a single one three days after cessation of the drug therapy. The dosage was 3 Gm., 2 Gm. and 2 Gm. in three days. Similar results have been obtained with even smaller doses. Prophylactic treatment has been used successfully in the United States Army in the course of the past few months. Thus one may see that small doses of sulfadiazine are capable of killing the organisms in persons designated as carriers. Patients with acute mild meningococcic septicemia can be cured by 8 to 10 Gm. in divided doses and some have been observed to recover spontaneously. Chronic septicemia clears up on doses of 3 or 4 Gm. a day given for from five to seven days and subacute septicemia responds to about the same dosage. Full blown meningitis responds more consistently than does acute severe septicemia. In most cases meningitis is controlled by an initial oral dose of 4 Gm. of sulfadiazine followed every four hours with 1 or 1.5 Gm. by mouth. In cases in which the infection has progressed further with more organisms and the development of pus somewhat larger doses may be required and more prolonged treatment may be necessary. The more severe form of meningitis may require an initial intravenous dose of sodium sulfadiazine 5 to 8 Gm. depending on the patient's weight to be followed by further intravenous therapy if the drug does not persist at an adequate level in the blood. Finally the patients with fulminating septicemia those who if untreated frequently die within two to four hours after first reporting off duty need immediate adequate intravenous treatment supplemented by active treatment for the dehydration and shock in which they are seen. Here again 5 to 8 Gm. of sulfadiazine is given as soon as the clinical diagnosis is reached. From these remarks it is clear that the varying degrees of severity of meningococcic infection require different forms of treatment (table 5). If the infection is of the milder type the blood may be cultured and the spinal fluid examined before treatment is begun but if the infection is overwhelming, not a single minute should be lost in starting treatment. In large station hospitals where most of the patients with fulminant infection have been treated slight variations in the routine have been elaborated. There is uniform agreement as to the need for immediate intravenous treatment and equally uniform agreement as to the need for restoring body fluids as rapidly as possible. Lieut. Col. Worth B. Daniels finds that

giving the sodium sulfadiazine in 1,000 cc of isotonic solution of sodium chloride starts both chemotherapy and restoration of fluids at the same time. At the station hospital where he is chief of the medical service the best results were thought to be obtained by a somewhat smaller initial intravenous dose (3 Gm or 3.5 Gm). In most cases this is followed by 1,000 cc of 5 per cent dextrose solution, and fluid is given thereafter in amounts adequate to insure abundant urinary output.

Complications.—The one disturbing complication encountered in treatment with sulfadiazine is hematuria which is often associated with retention of nitrogen and only rarely with oliguria and anuria. It is caused by crystallization of the superconcentrated form of the drug in the tubules of the kidneys. It has been known for some time that this crystallization will not take place in alkaline solutions and that crystallization depends on a combination of concentration and acidity of the solution. That this holds true for human urine was shown graphically by Fox, Jensen and Mudge.¹⁵ Two patients treated at the Presbyterian Hospital, New York, were given enough of the drug intravenously to produce blood levels of 69.5 mg and 138 mg per hundred cubic centimeters respectively. Extremely large doses of alkali, 10 to 20 Gm of sodium bicarbonate daily, were given to keep the urine at pH 7.5, and fluids were forced diligently. As soon as the pH fell slightly the crystals appeared in the urine. In cases of meningococcic infection one is not dealing with such extremely high blood levels, but it is thought by most clinicians who have treated these patients for fulminating disease that it is essential to obtain promptly levels between 15 mg and 20 mg per hundred cubic centimeters. It must be pointed out, however, that these particular patients when first seen are dehydrated and in a condition of shock which tends to lessen renal blood flow. If the body is conserving fluids the urine will be extremely concentrated so that the percentage of drug in the tubular fluid may reach disproportionately high levels. This concentrated urine has a tendency also to be strongly acid, and forcing fluids must be undertaken at the very earliest moment. It has been the experience throughout the entire southeastern section that a large percentage of patients given intravenous medication develop hematuria, often gross hematuria, soon after the first intravenous injection. Retention of nitrogen may or may not accompany hematuria and occasionally develops even in the absence of hematuria.¹⁶ It should be emphasized, however, that when an adequate urinary output has been established and a change made at the same time from sulfadiazine to sulfanilamide treatment, with the use of alkali, the hematuria promptly clears up and retention of nitrogen disappears. In no case has there been evidence of more than temporary functional renal impairment, and I have seen nothing in the literature to suggest permanent renal damage from sulfadiazine.¹⁷ At one post this problem seems to have been solved successfully.¹⁸ Desperately ill patients are treated intravenously immediately with 1,000 cc of a sixth-molar solution of sodium lactate, followed by 5 Gm of sodium sulfadiazine in 5 per cent concentration in distilled water, followed by 1,000 cc

of a sixth-molar solution of sodium lactate, followed more slowly by 1,000 cc of a 5 per cent dextrose solution in 0.9 per cent saline solution. No patient treated by this technic has developed hematuria, in every one the urine was alkaline, diuresis was abundant and the blood level the following morning was usually in the region of 12 to 14 mg per hundred cubic centimeters. There is every reason to believe that this or some modification of this technic will eliminate hematuria from crystallization of a sulfonamide compound and at the same time afford a prompt high blood level of the drug.

At certain stations the subcutaneous injection of sulfadiazine in 0.5 per cent concentration in isotonic solution of sodium chloride has been advocated, and this injection is often given soon after the first intravenous injection. It is thought that such a procedure effects a slower rate of absorption and possibly a steadier blood level. At other stations excellent results have been obtained by using a Levine tube. Through this tube fluids, nourishment and salt as well as medication can be administered. In some of the more desperately ill patients adequate blood levels have not been obtained by oral use of the drug even when extremely large doses were given. For this reason when the ordinary dosage of 1 to 1.5 Gm every four hours does not maintain an adequate blood level intravenous medication with doses of 2 Gm should be employed as an extra. Usually after one or two doses have been given intravenously the patient regains consciousness to a degree which permits subsequent doses to be given by mouth.

Additional therapeutic measures have been used and should be mentioned. In cases of shock due to toxemia blood transfusion and plasma infusion have been used with apparent benefit. Also in cases of shock adrenal cortex extract has been used in doses of 30 cc to 50 cc followed by smaller doses at frequent intervals with much benefit in the eyes of six observers. Other observers have not been able to convince themselves of beneficial effects. Epinephrine administered by the constant drip method seems to have had brilliant results in a few cases. Desoxycorticosterone acetate has been used but with a more delayed action and without clear-cut evidence of benefit. It seems possible that in patients whose adrenal glands have been damaged by hemorrhage, but who have been cured of the bacterial infection, this synthetic drug might play a beneficial role after the early stages. Three such patients are thought to have been cured in the series now being reported, and possibly many others.

Blood Level of the Drug.—Exact information is not at hand as to what blood level of the sulfonamide compound is adequate in the treatment of each of the various clinical forms of meningococcic infection outlined in this article. In the literature are reports of cures from a dose as low as 1 Gm.¹⁹ At the opposite end of the scale is the widespread experience that in desperately ill patients large doses by mouth fail to give levels over 2 or 3 mg per hundred cubic centimeters. In the middle of the scale is a large group of patients who have recovered from clearcut meningitis on ordinary oral doses, whose blood level either reached 10 to 12 mg or stayed down between 3 and 5 mg per hundred cubic centimeters. Attention should be drawn to an article

19 Quoted by Dingle, J. H. and Finland Maxwell. *Dis. Treatment and Prevention of Meningococcic Meningitis*. War No. 2: 158 (Jan.) 1942.

by Dowling Hartman Feldman and Jenkins²⁰ comparing the mortality rates from lobar pneumonia in two series one treated with an initial dose of 5 Gm by mouth and 1 Gm every four hours and the other series with just half this dose. It was shown that the mortality rates were identical. It seems likely then that in many instances of meningitis excessive doses have been given and an excessive blood level has been maintained. On the other hand it seems clear that the more severely infected patients require higher blood levels than the patients whose disease is mild and moderate. This was shown to hold true for laboratory animals (mice) by Long Bliss and Feinstein²¹ who stated that "It is to be noted that the larger the dose of the drug the greater was the survival rate of the mice and that the average duration of life was longer for the more heavily treated mice." Patients have been observed who after two or three days on ordinary dosage have shown noticeable improvement when the size of the dose was increased. No harm has been seen from blood levels of between 15 and 25 mg per hundred cubic centimeters, and hematuria can be avoided by forcing fluids and alkalis. The problem arises as to whether or not administration of excessive amounts of fluid washes large amounts of the drug out of the system, thereby reducing the effectiveness of the treatment. It is thought that in most infectious diseases the urinary output should be maintained at between 1,500 and 2,000 cc in twenty-four hours and this has proved satisfactory in cases of meningitis. The intravenous injection of fluid in the form of isotonic solution of sodium chloride and 5 per cent dextrose and sodium lactate and the administration of fluids by mouth or Levine tube should be regulated to the needs of the individual patient. Until further evidence is at hand the best rule is to obtain promptly a blood level of 12 to 15 mg per hundred cubic centimeters and maintain a level of 10 to 12 mg per hundred cubic centimeters until the patient is out of danger. After the first few days levels of 7 to 10 mg per hundred cubic centimeters or even lower will suffice to complete the cure. It is my impression that the level of the drug in the spinal fluid has little practical significance since the systemic, cerebral and meningeal locations of the infection are supplied with the drug by the blood stream and those organisms which reach the spinal fluid are essentially harmless.

Antimeningococcus Serum and Antitoxin—The problem of serum therapy has been largely discussed. My colleagues and I have nothing to add except that it is the universal opinion throughout the Fourth Service Command that ordinary antimeningococcus serum has been of no additional value in treatment. There is one group of patients who seem to have been benefited by meningococcus antitoxin namely the group with septicemia. Some of these are so toxic that they die in a few hours. It is clear that antibacterial treatment must have time to become effective and this time can be lengthened it is thought, by the use of antitoxin. This whole subject is in the course of being evaluated, and at the present time the supply of meningococcus antitoxin is extremely limited. The antitoxic property is contained also in concentrated rabbit antimeningococcus serum but here again the supply of this product is extremely limited. Answers from a recent question-

nnaire throughout the army hospitals of the southeastern area reveal that 10 of 17 medical officers who have used antitoxin in more than one case believe it has had a distinct beneficial effect, noticeable within a few hours. One hundred and thirty-six of the desperately ill patients were given antitoxin, and at ten station hospitals the effect was thought to be either beneficial or extraordinarily beneficial in 56 cases. In 3 cases an immediate beneficial effect was noted. Those who are not impressed by its value point out that similar improvement is noticed in a few cases within two or three hours after the injection of sodium sulfadiazine. Final proof of the benefit of antitoxin therapy is not at hand. A warning must be issued that every precaution in the use of serum must be scrupulously observed, and patients with a history of allergy or recent serum treatment or those showing a positive cutaneous test should not be treated with serum or treated only after careful desensitization has been effected. There is no reason to believe that serum therapy properly administered is more dangerous to a patient in shock than to any other patient. Nor is there any reason to believe that intravenous injection of serum places any more strain on the heart and the peripheral vessels than intravenous injection of any other fluids. As long as anaphylaxis is avoided and fluids are injected into the vein slowly, no particular fear of this form of treatment need be entertained.

It is interesting to observe a graphic example of what early diagnosis and prompt efficient treatment can effect. During the first two months of this outbreak many unusual cases of meningococcic infection escaped early recognition by unit medical officers, various officers of the day and members of various sections of the hospital staffs until the disease was fairly far advanced. This with other factors is reflected in the mortality rates of 12.8 per cent for the month of December and 7.3 per cent for the month of January. During these two months only 317 patients with meningococcic infection were seen. In the next two months, after the technique of early diagnosis and treatment was learned 761 patients were treated with a mortality of only 2.1 per cent. This excellent result was obtained by close cooperation among all the members of the army medical corps and by the individual personal attention of one or more officers who have been in charge of the patients at each of the various station hospitals. Cases of fulminating infection are still occurring, however, and are the ones which form the basis for the present mortality rate. In the month of April (which includes five weeks) there were 15 deaths out of 531 cases so that although the outbreak is definitely receding in some areas it is continuing with full virulence in others.

COMMENT

The experience with a large number of cases of meningococcic infection during the past two months has provided opportunity for wide employment of modern chemotherapy. The mortality rate in the first two months was reduced to one fourth of the rate in the last war and as experience and proficiency in diagnosis and treatment were gained this low rate was cut to one fourth, or 2.1 per cent, in 761 cases occurring in the Army throughout the seven Southern states during the months of February and March. The feasibility and effectiveness of large scale prophylactic use of sulfadiazine in the reduction of carriers and the prevention of cases are being demonstrated. It has been possible then to compensate by improved methods of

treatment and prophylaxis for the rapid training program which necessitated fatigue exposure and crowding of unseasoned troops. It seems safe to prophesy that in succeeding years the case rate can be greatly reduced by prompt prophylactic treatment at suitable points, particularly among unseasoned troops. It seems equally safe to prophesy that the mortality from the cases that do develop will be held to low levels although the occasional cases of fulminating disease probably will continue to produce a small number of deaths.

SUMMARY AND CONCLUSIONS

In a series of 1518 cases of meningococcic meningitis and septicemia the early mortality rate of 88 per cent in 317 cases was lowered during February and March to 21 per cent in 761 cases.

Two thirds of the cases developed among new troops. Of 55 fatal cases 80 per cent developed among new unseasoned troops.

Of 46 cases coming to autopsy 18 showed hemorrhage into the adrenal glands. This is regarded as an index to the severity of the septicemia and presents an additional feature for therapeutic consideration.

Early diagnosis and prompt skilful treatment based primarily on administration of suitable sulfonamide compounds will still be important even if prophylactic chemotherapy proves highly effective.

THE TREATMENT OF BURNS OF THE EXTREMITIES

WITH CLOSE FITTING PLASTER OF PARIS CASTS

STANLEY M. LEVENSON, M.D.

AND

CHARLES C. LUND, M.D.

BOSTON

Plaster casts have been used occasionally for many years by many surgeons for special indications in the care of surface burns. They have had particular use as splints to prevent deformity. For the most part such casts have been used in the secondary treatment of burns and have been well padded and loose fitting. Frequently they have been bivalved early to provide for frequent changes of whatever dressings were used under them. Lohr¹ in 1934 advocated the use of plaster casts over applications of cod liver oil ointment in the treatment of early burns. He attributed his good results chiefly to the cod liver oil. Roulston² in 1941 applied casts to burned extremities after maximum swelling had already occurred and infection was present. It was his opinion that epithelization and return of function were more rapid in these cases than in similar cases treated by other methods. Stonham³ in India treated old burns in closed plaster and gave the opinion that there was more maceration and persistence

of infection than when the wounds were left open. Zeno⁴ between 1937 and 1939 published a number of articles in several countries on the use of plaster casts in fresh burns. In the two of these articles studied⁵ the articles and one illustration indicate that tightly fitting casts were not used. Joints above and below the burn were immobilized but the cast was not closed over the end of the extremity. Casts were used for body burns as well as for burns of the extremities. Zeno felt that the good results obtained resulted from the immobilization provided by the casts. Afonso⁶ uses fairly close fitting casts over a thin tannic acid eschar. He presents abstract case reports on 8 cases with good results. Trueta⁷ recommends a close fitting cast for burns of the extremities, back and neck. He applies them over a thin tannic acid eschar after debridement. Most of his experience was with cases in which maximum swelling had occurred before the cast was applied. Cohen⁸ also treated a few similar cases with casts but without tannic acid. Barnes⁹ has recently reported the use of close fitting casts for burns of the hands, using a technic identical in principle to that reported here. It differs only in the use of debridement, in the use of less gauze to absorb secretions and in the insistence on suspension.

The possibility that plaster casts might serve a useful function besides providing rest and protection in the treatment of burns was not appreciated until the physiologic studies of Glenn, Peterson and Drinker¹⁰ and of Glenn, Gilbert and Drinker¹¹ indicated the harm produced by the swelling of the burned tissues. They also showed that the application of a close fitting plaster cast immediately after the burn would prevent swelling and at the same time the circulation in the burned extremity was unimpaired, whereas the circulation in the untreated foot showed definite indications of impaired capillary flow. Barnes and Trueta¹² had already shown that swelling could be prevented in this way.

In their experiments Glenn and his co-workers¹¹ pointed out certain specifications that must be followed if the closed plaster cast treatment is to be fully successful. First, the burn must be so located that the plaster may extend a few inches above the upper edge of the burn. Second, the plaster must be closed at the lower end and fit evenly and closely to the skin at all points. Third, compression of the tissues at

the time of application must be avoided. Fourth the benefits of the treatment decrease according to the amount of swelling that precedes the application of the plaster. Their demonstration of the safety, comfort and good end results secured by this method were so impressive that application of the method to human burns has been made although it is seldom possible to treat the latter before some swelling has occurred.

METHOD

If shock or other systemic disturbance is present it is treated by accepted practices at the time the cast is applied. There is but little shock caused by the treatment itself as no anesthesia, debridement nor cleaning is done except for the removal of large pieces of loose, hanging skin. This preliminary procedure is recommended for human burns by Cope¹³ and has been demonstrated by him to give good results when combined with the pressure dressings of Allen and Koch.¹⁴

One layer of sterilized petrolatum gauze is applied to the skin over the whole area to be covered by plaster. This is fitted exactly and is carefully placed between the fingers. This petrolatum gauze is cut from 44 mesh 3 inch wide rolls of bandage. This layer is covered with four layers of sterile open mesh gauze fitted carefully without overlapping. The gauze does not go between the fingers but does surround the thumb. Boston City Hospital abdominal sponges happen to be

Fig 1 (case 1) — Appearance of hand before treatment. Note broken and unbroken blisters. Sooty appearance from electric flash.

folded in such a way, 24 inches long and 4 inches wide, that they are convenient for this purpose. Very thin plaster slabs are then moistened and molded over the extremity front and back. A thin layer of rolled plaster completes a nearly skin tight, light well fitting plaster which extends 3 to 4 inches above the burn. The fingers are placed in a semiflexed position. Fifteen hundred units of tetanus antitoxin is given at once and this dose is repeated in five days. Sulfadiazine is started in twelve to twenty-four hours only in the cases in which in addition severe burns are present in other parts of the body. It is continued as long as it seems to be indicated. The original cast is left in place for fourteen days. If the burn has not healed at the time of its removal, another is applied at once and left on for a further period of fourteen days, since infection it present sets in motion a train of events (increased lymph flow, swelling and so on) fundamentally similar to that following the original thermal injury. Further treatment if necessary after the fourth week is by other methods. Surface cultures are taken on admission and at each subsequent dressing.

REPORT OF CASES

All the burns studied in this series were of the hands and arms. It is our intention to treat burns of the feet and legs in the same way but no suitable cases have been available to date. The cases are numbered in order of admission to the hospital. They are divided

Fig 2 (case 1) — After five days. Note median position of fingers. Slight exudate stains the cast.

into two groups. Group 1 is made up of those with burns that proved not to have total destruction of skin in any areas of the hands or arms (second degree burns) and group 2 of cases with burns of the hands that have proved to have destruction of full thickness of the skin in one or more areas (third degree burns).

GROUP 1

CASE 1 (Figs 1-5) — An electrical worker aged 33 swung a lantern against a third rail. The electric flash knocked him down. Examination showed the left hand covered on both sides with soot, slight swelling and a few intact and many ruptured blebs of skin. The surface area involved was about 2 per cent. Cultures were taken from the surface and petrolatum gauze strips and a cast applied ninety minutes after the time of injury. During the first forty-eight hours there

Fig 3 (case 1) — After twenty-four days. Second cast removed. Note ability to flex hand.

was a dull pain in the hand and wrist but no throbbing or paresthesia. At twenty-four hours there were slight edema and redness proximal to the cast for 2 inches on the mesial side. Because of the swelling he was given oral sulfadiazine for one week, starting at thirty-six hours. The swelling subsided in two days. There was no lymphadenitis or lymphangitis. He was afebrile throughout. A small area of staining from exudate appeared on the cast. The culture from the burn

surface was reported to show alpha hemolytic streptococcus, hemolytic *Staphylococcus aureus* and *Bacillus subtilis*.

At eleven days the cast was removed. This was a painless procedure. There were small amounts of moist exudate present, particularly on the interior wrist. The layer of soot and dirty epithelium was intact on the hand. Because of the deeper burn at the wrist which had not completely healed a new

Fig. 4 (case 1)—After twenty four days. Second cast removed. Note hand in median position.

cast was applied. Culture at the wrist showed alpha hemolytic streptococcus, hemolytic *Staphylococcus aureus*, *Clostridium perfringens* and *Pseudomonas aeruginosa*, with the latter predominating.

During the next two weeks absence of fever and pain continued and there was no swelling proximal to the cast. At twenty-four days from injury the second cast was removed. The wrist burn was partly healed.

The burns of the hand had completely healed under the dark layer of desquamating epithelium. Motion of the fingers was fairly good. There was no pain. A small petrolatum dressing was applied to the wrist. At five weeks all desquamating epithelium was off the hand, the wrist was healed and motion in the hand and fingers was normal.

CASE 4 (Figs 6 and 7)—An electrician aged 34 was burned in an explosion of an oil heater. He had burns with blisters and broken blisters of both sides of all fingers, both hands and both wrists and of the right forearm, elbow, part of the arm and part of the face. About 10 per cent of the surface area was involved. There was also some respiratory irritation from inhalation. Surface cultures were not taken on admission. Casts were applied over petrolatum gauze dressings ninety minutes after the accident. The patient was moderately dyspneic

Fig. 5 (case 1)—After forty days. Complete healing with excellent function was present for ten days before this picture was taken.

and there were crepitant rales throughout the lung fields. The temperature rose to 102.0 F the first two days, fell to 100 on the fourth day and remained normal thereafter. Oral sulfadiazine was started at twelve hours. It is our impression that this fever was of pulmonary origin. The casts were removed on the eleventh day and second casts were applied. There was no swelling or sepsis, and minimal exudate was present. Motion was good. Cultures at this time showed alpha hemo-

lytic streptococcus, hemolytic *Staphylococcus aureus*, *Bacillus subtilis* and *Pseudomonas aeruginosa* present on both hands. At twenty-three days, when the second casts were removed, healing was complete and function was good.

CASE 5—A member of the fire department aged 43 had to escape from a roof through a wall of flame. He received a first degree burn of his face, small second degree burns of both knees and second degree burns of both hands. The surface area involved was about 5 per cent. Many broken blebs were present. The dorsum of the right hand and fingers was covered with large unruptured blebs. Without cleaning, petrolatum gauze and casts were applied to both hands and forearms two hours after the injury. His hands were very comfortable in the casts and there was no fever. At two weeks the casts were removed. The left hand was healed and normal. The right hand was covered with a thick layer of desquamating epithelium. Motion of wrist was normal and of fingers 60 per cent. A cast was applied to this hand for two weeks more. At four weeks healing was complete and motion of fingers was very good.

CASE 6—A member of the fire department aged 30 was burned at the same time and in the same way as patient 5. His burns were less severe. There were burns with blisters of the dorsal aspect of all fingers and of both hands and additional burns of the face. The total area was about 3 per cent. Casts were applied to both hands up to the midforearm

Fig. 6 (case 5)—Eleventh day. Condition on removal of first cast. Note free flexion.

Cultures on admission showed "no growth." Normal recovery occurred. On removal of the casts at fourteen days complete healing had occurred. Motion was normal. There was no exudate on the dressing.

CASE 7—A schoolboy aged 9 years lighted a pile of gun powder and received burns of the right hand and face. There were blisters on the right hand and fingers and a large denuded blister of the right wrist. A moderate amount of soot was present in the burned skin. The total area was 4 per cent. Cleaning was not done. Petrolatum gauze and a plaster cast were applied two hours after the accident. Culture showed "no growth." The temperature went daily to 100 F for one week, with no rise thereafter. The cast was removed on the fourteenth day, when healing was complete and function normal.

CASE 8—A man aged 63 received gasoline flame burn of the second and third degree of the entire right leg and thigh, the inner aspect of the left leg and thigh, the lower part of both buttocks, and a long narrow strip across the abdomen. Parts of these burns were dirty dead white, parts were leathery and still other parts were oozing from broken blisters. The right hand also was burned and showed blebs and broken blebs over the dorsum of all fingers, the hand and wrist. The total area of the body burned was 25 per cent. A cast was applied to the hand and forearm, but other treatments to the leg and abdomen. He was given 1,500 cc of plasma in the first ten hours.

The hand was very comfortable in the cast. On the fourth day he developed bronchopneumonia, although on sulfadiazine

treatment from the twelfth hour. After a week he began to improve but remained a very sick man. On removal of the casts at fourteen days the hand was completely healed and motion was normal.

CASE WITH DEEP BURNS OF THE HAND

CASE 2—A chronic alcoholic addict aged 32 set his bed on fire smoking. He was moderately intoxicated and had a blood plasma alcohol level of 0.026 Gm per hundred cubic centimeters. There was a deep burn of the whole circumference of the right arm from the finger tips to the axilla. It extended over the shoulder and down the flank to the lateral abdominal wall. This whole area was burned so that the skin was leathery and not weeping. There was a less severe burn of the left hand from the finger tips to the upper forearm. The total area was 20 per cent. Both hands and arms were placed in plaster casts. On the right arm a petrolatum dressing compressed with an Ace bandage was continued above the cast to cover the remainder of the burn on the shoulder and axilla and over the flank.

During the first twenty-four hours he was given 4000 cc of plasma and in the second 1,000 cc. His blood pressure was always maintained but his urine output was only 500 cc the first twenty-four hours. He went into very severe delirium tremens that did not respond well to very large doses of vitamins or to the usual doses of paraldehyde. On the fourth day he had some symptoms of pneumonia but adequate chest

Fig. 7 (case 2)—Twenty-third day. Condition after removal of second casts and cleaning. Complete healing and complete return of function.

examination could not be made because of large body dressings. On the eighth day spastic symptoms suggested meningitis, but a lumbar puncture secured normal spinal fluid. This stiffness did not suggest tetanus and improved steadily up to the time of his death. Death occurred on the ninth day.

The casts were removed post mortem. Complete destruction of the skin over nearly all the burned area was seen. This destruction was as severe where no cast was applied as it was under the cast. There was much more moisture and other evidence of infection in the areas not treated with the cast than under it. However the skin of the third fourth and fifth fingers of the right hand was almost completely destroyed, so that the posterior tendons were exposed as well as the proximal interphalangeal joints. In spite of this destruction there was obvious circulation still maintained to the tips of these fingers on the palmar surface. The autopsy showed that death had occurred as a result of massive bronchopneumonia.

CASE 3 (Figs. 8, 9 and 10)—A housewife aged 35 was removed deeply intoxicated and burned from a burning apartment. A strong odor of alcohol was present and the blood plasma alcohol level was 0.056 Gm per hundred cubic centimeters. Crepitant rales were present in both lung fields. There was definite exposure to smoke inhalation. There were burns of the whole hand and forearm to 1 inch above the elbow. Over this area most of the blisters had broken and the epidermis

was missing. Much of the skin was leathery and dry, especially the last three fingers and a large area below the elbow. These areas appeared to be third degree burns. There was also a burn of the lateral surface on the left leg and buttock that was dry brown and leathery in appearance. There were other severe burns of the right buttock and slight burns of the face. The surface area involved was 15 per cent. A cast

Fig. 8 (case 3)—Thirteenth day. Cat and dry gauze removed. Petrolatum strips in place. No or small amount of exudate.

was applied to the arm up to the axilla with the elbow extended to 120 degrees. Other dressings were applied to other areas. During the next few days the patient was very sick with delirium tremens and pulmonary irritation.

At thirteen days the cast was removed. It was remarkable in two ways. First there was but little pain in removing it and secondly there was very little discharge on the dressing. There was dry leathery natural eschar of the skin of the medial three fingers. Another cast was applied and left on ten days. When removed, it was seen that the extensor tendons of the medial three fingers were exposed over the proximal interphalangeal joints. There was but little pain and tenderness and little swelling. Motion was good even in these fingers. Following removal of the second cast, treatment was shifted to irrigation in a "Bumby" envelop. She was ready for grafting on the fifty-second day but the presence of scarlet fever in the ward caused a delay. On the sixty-sixth day Padgett dermatome grafts were applied to all areas of granulation on the hand forearm and leg. On the seventy-sixth day at the first dressing of the grafts all had taken except over the exposed bones of the three lateral fingers.

Fig. 9 (case 3)—Thirteenth day. Petrolatum removed. No or minimal swelling.

COMMENT

A satisfactory treatment for burns should be locally and generally harmless, comfortable and easy to apply from widely available materials of minimum bulk. It should also give protection against the invasion of harmful organisms and protect the natural defenses of the body in their contest to control those already present. It should reduce as much as possible the

flow of plasma or exudate from the burned surface or the collection of edema under it. It should also need a minimum of attention after application. Finally it should allow the natural healing processes of the body to create and maintain as nearly optimum conditions for the removal of dead tissue and for the growth of new cells as possible. This will be recognized by most readers as practically identical with the position that H. W. Orr has maintained for years in connection with infections. He has just published a fine discussion of this subject.¹⁵

ABSENCE OF LOCAL HARM

It is difficult in clinical studies of burns to prove whether a given treatment is harmful or not because of the impossibility of estimating accurately in all cases at the time of initial treatment the extent of the damage already done by the burns. Certainly the early return of function that has been seen in these cases immediately after removing the casts is an indication that the method is usually harmless. It is further our impression that no areas of second degree damage have been converted to third degree by this method and that epithelialization takes place at a rapid rate.

A certain warning concerning the technique of application should be given as it is theoretically possible to

Fig. 10 (case 3)—Twenty-third day. Large areas of skin have sloughed, exposing tendons. At this time there was a surprising range of motion.

do great damage by the improper application of these casts. The cast must extend over the tips of the fingers or toes even when the burn does not, and it must not provide any zones of increased pressure at any point. Glenn, Gilbert and Drinker¹¹ present a photograph of a badly swollen foot when a cast was applied to the lower part of the leg of a dog without including the foot.

ABSENCE OF TOXIC ABSORPTION

Tannic acid and picric acid have been absorbed from burns treated with these materials to such an extent that liver necrosis and death have been attributed to this absorption.¹⁵ Nothing harmful can be absorbed from the surface of burns treated with this method except the products of the burn itself or the products of bacterial invasion. Barnes and Trueta¹² have shown that absorption of foreign materials is greatly delayed from immobilized tissues. This finding is easy to understand in the light of the work of Glenn¹⁰ and his associates, who have shown definite decreases in the flow of lymph from burns treated with casts compared with ones not thus treated. A cast also protects against reinfection from new organisms. At the same

time, according to Barnes and Trueta,¹² the organisms already present either die out or become harmless. This point of view is confirmed by the experience of Cope,¹³ who found a remarkable tendency for organisms to become harmless under the pressure dressings that he used.

COMFORT

From the start of treatment to complete healing the lack of pain experienced by these patients has been remarkable. As soon as the cast is applied, pain disappears. There may be a slight dull ache, experienced by 3 of the 8 patients in the first three days. After this there is no discomfort and the arm in the cast can be moved freely. No throbbing pain, anesthesia or paresthesia has been noted. The patient can move the fingers a millimeter or so inside the cast, but this motion is painless. Removal of the cast at fourteen days is done without the aid of analgesia or anesthetic as practically no pain results, even during the use of a cast cutter. Apparently the lack of edema or the absence of active infection in the tissues avoids the condition of extreme sensitivity to handling that is frequently seen at this time in comparable burns.

EASE OF APPLICATION

Close fitting plaster casts are relatively easy to apply, and the bulk of material (excluding water) is very little. Most doctors need no additional training in methods of applying plaster casts, although some may need encouragement before they will leave out the bulky materials customarily used in padded casts. Any man who has applied a satisfactory "skin tight" plaster to a fracture will have no difficulty at all with these casts. In our experience it is difficult for the ordinary physician to apply a Koch dressing to a burn. It necessitates quite a long experience with such dressings before a really satisfactory one is made. The bulkiness of the materials needed, especially the mechanic's waste, cellucotton or sheet wadding, may make it difficult to stock sufficient supplies where transport or storage is scanty.

LOSS OF PLASMA

The minimal subcutaneous edema in and adjacent to the burned area possible under the cast, and the small amount of surface ooze that occurs, reduce to some extent the need for plasma replacement. If the area treated by the cast is extensive, the saving should be considerable.

INFECTION

Superficial sepsis was minimal in all cases, with only a small amount of exudate present on the dressings. Cultures showed a mixture of organisms, with none predominating except in 1 case in which *Pseudomonas aeruginosa* was predominant. Self-limited cellulitis unaccompanied by systemic reaction, was present in 1 case. None of the 3 patients whose burns were limited to the hands and arms developed any fever.

AFTER-CARE

During the time the cast is on, no time needs to be spent in doing dressings to the casted area. If the cast cracks from being made too thin, repair is easy (The cast should be as thin as possible.) If the patient has to be moved during the period when the cast is on, no better protection against the normal trauma of transportation can be devised.

¹⁶ Glenn, Peterson and Drinker¹⁰ Glenn, Gilbert and Drinker¹¹

HEALING

In the last analysis healing can take place only when natural defenses have created such conditions at the site of healing or temperature, pH, salt content of the fluids, oxygen and carbon dioxide tension, nutritive elements and enzymes that tissue cells can grow. In addition toxic substances must be absent. Interference or disturbance of the environment of the injured area is therefore very important because with each change or dressing one or more of these factors may be upset and hours or days must elapse before proper conditions can again be achieved. Under one of these casts such disturbances of accidental nature are almost entirely prevented and those of deliberate nature (which may be just as harmful as the accidental ones or even more harmful) such as arise from the curiosity of the doctor to see what is happening are largely discouraged. We believe that the healing of the skin has been as rapid as in similar cases treated in other ways and that return of motion has been more rapid.

INDICATIONS FOR THIS TREATMENT

In this series cases with burns of the hands, forearm and arms have been treated. In only 1 instance (case 2) did the burn extend above the cast. A pressure dressing was applied above this cast. There was no evidence of impairment of circulation. Zeno⁵, Alonso⁶ and Trueta⁷ have all used plaster casts on areas that we have not treated as yet. We are sure that this treatment is indicated for burns of the feet and legs. As we gain experience in the method we may well extend the indications more widely.

SUMMARY AND CONCLUSIONS

1. Close fitting plaster of paris casts have been used in the treatment of burns of twelve hands on 8 patients.

2. The physiologic experiments of Glenn and his associates formed the scientific background for this treatment.

3. The treatment is easy of application. The materials needed are widely available and of little bulk. Ideal protection against intercurrent infection and against the trauma of transportation is afforded.

4. The prevention of swelling and the protection provided by the treatment have resulted in comfortable, rapid, uncomplicated convalescences and in excellent functional results.

ADDENDUM

Up to September 7, 14 additional patients have been treated by this method with casts applied to sixteen arms and hands, four chests and four legs. Four of the arms and hands and all the legs had third degree burns. The results of these applications of plaster have been very satisfactory.

319 Longwood Avenue

By-Products from Sewage—Trucks rumbling through the streets of oil-starved Germany today are operating on methane gas, obtained as a by-product from municipal sewage treatment plants. In Bradford, England, sewage disposal processes are yielding 500 tons weekly of vitally needed grease. In the United States a big steel plant is buying huge quantities of liquid effluent from a city sewage plant because existing industrial water supplies are inadequate to meet expanded output. These three examples dramatize what might be considered the ultimate in driving salvage from waste. They focus attention on one of the least suspected sources of valuable by-products—the city sewage disposal system.—Clarey, Edward I. Dollars from Sewers. *Scientific American*, September 1943, p. 103.

Clinical Notes, Suggestions and New Instruments

FAILURE OF NEPHRECTOMY TO INFLUENCE HYPERTENSION IN UNILATERAL KIDNEY DISEASE

EDWARD WEISS, M.D., PHILADELPHIA, AND
HERBERT CHASIS, M.D., NEW YORK

Experimental production of hypertension by partial occlusion of the blood supply to one kidney¹ has suggested that intrinsic unilateral renal disease in man can similarly cause arterial hypertension. The acceptance of this thesis has led to the search for unilateral disease in hypertensive patients and when found to nephrectomy of the suspected kidney. Seventy-six published case reports of attempts to cure hypertensive disease in man by removal of a diseased kidney have been reviewed in detail by Smith, Goldring and Chasis.² In the opinion of

Nephrotic left kidney weighing 53 Gm.

these authors, in only 7 of the 76 patients has nephrectomy been successful in reducing the elevated blood pressure to the normal range.

It has been argued that failure to reduce the blood pressure in a patient with a long-standing unilateral kidney disease and hypertension might be explained on the basis of irreversible vascular changes in the remaining kidney capable of maintaining the hypertensive process. This report is made because nephrectomy failed to reduce the blood pressure of a patient in whom postoperatively the remaining kidney is not diseased and has a normal blood flow per unit of functioning renal tissue.³

From the Department of Medicine, Temple University Medical School, Philadelphia, and the Department of Physiology, New York University College of Medicine, New York.

REPORT OF CASE

History—S. H., a white woman aged 34, seen in October 1941, complained of high blood pressure, headache and slight fever. She had been in good health until a year and a half before, when her fourth and last child was born. Following delivery she had a fever which lasted three weeks, and during this time there were occasional chills. For about six months she was relatively well, and then she began to feel weak and listless. She complained of headaches in the temporal region, described as dull, and at the top of the head, described as burning. Other aches and pains had been present and she also suffered from insomnia. The temperature and blood pressure were both found to be slightly elevated.

There were no other serious illnesses in the previous history. After the third pregnancy five years before there had been a febrile illness diagnosed as a "slight touch of pneumonia." The patient had been ill for only a week and was quite well afterward. The systematic review disclosed nothing of importance.

She did not know of any history of hypertension or cardiovascular renal disease in her family.

Unconscious feelings of guilt and hostility seemed to be important features of her personality. Outwardly passive and pleasant inwardly she exhibited a great deal of resentment toward her husband and her mother.

Effective Renal Blood Flow, Glomerular Filtration Rate and Maximal Tubular Excretory Capacity Before and After Left Nephrectomy

	Renal Plasma Flow (Cc per Minute)	Filtration Rate (Cc per Minute)	Maximal Tubular Excretory Capacity (Mg. Iodine per Minute)	Renal Plasma Flow Max. Tub. Excret. Cap. (Cc/Min)
Preoperative Observations—March 21, 1942				
Right kidney	86.2	81.2	4.34	87
Left kidney	4.7	17.0	3.0	18.4
Total	91.9	101.2	48.4	91
Postoperative Observation—June 5, 1942				
Right kidney	592.6	95.8	48.4	12.2
Normal*	191 ± 102.4	117 ± 15.6	42.6 ± 9.10	14.2 ± 2.0

* The diodrast clearance was used to measure the effective renal blood flow; the mannitol clearance to measure the rate of glomerular filtration; and the diodrast saturation method to determine the maximal tubular excretory capacity. Values given at the bottom of the table are based on observations in normal female subjects.

Physical Examination and Laboratory Studies—The general physical examination did not disclose any abnormalities. Gynecologic examination was negative. The eyegrounds showed mild attenuation of the retinal arterioles. There was no evidence of arteriosclerosis and no retinitis. There was moderate elevation of blood pressure, which varied between 150 to 170 systolic and 90 to 120 diastolic. There was an occasional slight elevation of the temperature to 99.3 F. Urinalysis and Wassermann tests were negative and the blood count was normal. The sedimentation rate was 14 mm and the basal metabolic rate was minus 6 per cent.

Culture of the urine showed many coliform bacilli, and an intravenous urogram showed that the left kidney was much smaller than normal with a deformity of the calices which suggested pyelonephritic contraction. The right kidney was larger than normal and presented a normal appearance.

Retrograde pyelography of the left side was then done, and this showed irregular and distorted major and minor calices which suggested a cicatricial deformity. This was in keeping with the diagnosis of chronic pyelonephritis. The same type of organism was obtained from direct culture of the left kidney.

The patient was placed on sulfathiazole medication, and the Addison count showed a slight excess of white blood cells and many sulfathiazole crystals. Medication was then changed to sulfadiazine, which was well tolerated. Cultures of the urine following the administration of sulfadiazine were negative.

The patient was studied again in December 1941. The blood pressure was higher than before, 185/135. Slight fever (99.5 F) continued. A left retrograde pyelogram was the same as before. Culture of the urine was negative.

Operative Findings—A small left kidney weighing 33 Gm was removed in April 1942 (shown in the illustration). The capsule was thin and stripped with ease. The capsular surface was definitely lobulated. The cut surface of the kidney showed a normal relationship of cortex and pyramids. The pelvic mucosa seemed of normal thickness and there was no gross evidence to suggest inflammation or scarring. The larger blood vessels showed nothing abnormal on gross examination. The lining was smooth and the contents resembled old blood.

Sections of the kidney were studied by Dr. E. E. Aegerter and by Dr. Irving Graef. It was agreed that the scarring was of the type commonly seen in healed or chronic pyelonephritis. This was confirmed by microscopic examination which showed that the indentations were the result of scarring typical of the late stage of pyelonephritis.

The glomeruli seemed almost normal in appearance and number. There were 47 glomeruli in a low power field compared with 62 in a normal adult kidney. Individual glomeruli showed no replacement fibrosis or reduction in size. There was no patchy cortical atrophy or failure of development of the tubules. There was arteriosclerotic involvement of the medium sized branches of the renal artery and hypertrophy of the afferent arterioles.

The section which included the pelvis and calices showed rich lymphocytic infiltration beneath the epithelium. The tubular remains in the scarred areas also exhibited the typical dilatation and colloid type of cast seen in pyelonephritic scars.

Postoperative Course—Following the operation the blood pressure was even higher than before, with levels of 170 to 200 systolic and 120 to 140 diastolic. The patient was seen about every two months. The last observation was in April 1943, twelve months after the operation. Symptoms were no different, although there had been a slight gain in weight. She "loses one ache and gets another." Fatigue and shortness of breath (sighing respirations) were now a prominent part of the clinical picture. It was concluded that the occasional slight rise of temperature did not indicate infection but was normal for the patient.

The glomerular filtration rate,⁴ the effective renal blood flow⁵ and the maximal tubular excretory capacity⁶ were measured in the separate kidneys preoperatively and in the remaining right kidney postoperatively.⁶ The results of these observations are presented in the accompanying table.

COMMENT

The preoperative observations on this patient revealed extreme functional impairment of the left kidney. The glomerular filtration rate, effective renal blood flow and maximal tubular excretory capacity were definitely reduced. The functional size of the diseased kidney was approximately one-seventh the normal kidney. These measurements also indicated the presence of a large number of impotent nephrons, that is, nephrons which had lost their excretory power but continued to act as conduits in conveying urine to the collecting tubules.

The glomerular filtration rate, the effective renal blood flow and the maximal tubular excretory capacity in the right kidney was increased above one half the mean normal value. This was interpreted as indicating hypertrophy of the right kidney, the stimulus probably being long-standing disease of the contralateral kidney. The ratio of renal blood flow to tubular excretory capacity, which expresses the amount of blood going to functioning tubular tissue, was decreased, indicating relative ischemia in this hypertrophied right kidney.

Postoperatively the right kidney shows an increase in effective renal blood flow, glomerular filtration rate and maximal tubular excretory capacity, this one kidney, functionally speaking, is now the equal of two normal kidneys. The ratio of blood flow to functional tubular tissue is now in the normal range.

⁴ Smith, W. W., Finkelstein, Norma, and Smith, H. W., "Excretion of Hexitols (Sorbitol, Mannitol and Dulcitol) and Their Derivatives (Sorbitan, Isomannide and Sorbitol) and of Endogenous (resembling Chromogen in Dog and Man)," *J. Biol. Chem.* 155: 211 (1947).

⁵ Goldring, William, Chasis, Herbert, Ransley, H. A., and Smith, H. W., "Relations of Effective Renal Blood Flow and Glomerular Filtration to Tubular Excretory Mass in Normal Man," *J. Clin. Invest.* 19: 739 (Sept. 1940).

⁶ Chasis, Herbert, and Redish, Jules, "Function of the Secretory Nephrons in Hypertensive Subjects," *Arch. Int. Med.* 70: 758 (1940).

The persistence of hypertension in this patient postoperatively indicates that the unilateral atrophic pyelonephritis was not causally related to the hypertensive process. Furthermore, the fact that the renal blood flow per unit of functioning tissue is in the normal range in the remaining kidney excludes the possibility that chronic irreversible vascular changes resulting in ischemia of this kidney is maintaining the abnormal elevation of blood pressure. The fact that the hypertensive process was of relatively short duration strengthens this view. It appears that the intrinsic unilateral disease present in this patient was not the cause of the arterial hypertension.

CONCLUSION

The removal of a chronic atrophic pyelonephritic kidney failed to lower the blood pressure of a hypertensive patient. The remaining kidney cannot be indicted for this failure since it is neither diseased nor ischemic. It is concluded that the intrinsic unilateral renal disease in this patient was not causally related to the arterial hypertension.

THE USE OF HUMAN FIBRINOGEN IN RECONSTRUCTIVE SURGERY

COMMANDER PAUL MICHAEL, MC V (S), USNR
AND

LIEUT. COMMANDER WALTER ABBOTT, MC V (S), USNR.

The successful application of the principles involved in the use of human fibrinogen is thought of sufficient and timely interest to report at this time. Work on animals has proved that both bovine and human fibrinogen may be used to good advantage as a bridge for tissue regeneration. The present case report presents the successful use of this substance in the treatment of a human patient.

REPORT OF CASE

History.—P. B., a man aged 27, was injured by a high explosive fragment on Nov. 19, 1942, sustaining a laceration of the right thigh. He developed a foot drop with paresthesias over the outer aspect of the thigh and foot. A month later he complained of a severe burning pain in the foot. X-ray examination revealed a foreign metallic body in the soft tissues at the middle third of the thigh. On March 23, 1943, a small

Fig. 1.—Microscopic section ($\times 150$) taken through the fibrinogen after being used in the body for over four weeks. There is very little inflammatory reaction and no evidence of absorption of the fibrinogen.

piece of shell fragment measuring 10 by 0.7 cm. was removed from the sciatic nerve and because of the denuded sheath human fibrinogen film was applied. (Fibrinogen was supplied to Comdr. R. R. Mazet (MC), USNR, by the Physiologic

Laboratory, Harvard University.) The film of fibrinogen was wrapped round the nerve and six weeks later the operative site was opened and the film removed. At this time healthy nerve tissue was observed with an excellent healing process in progress. The pain in the foot now had subsided.

Pathologic Examination.—The first specimen received in the laboratory (March 23, 1943) consisted of a piece of metal measuring 15 by 0.7 cm. Also present were several irregular

Fig. 2.—Section ($\times 100$) taken through the nerve sheath with attached fibrinogen on the surface. Note the glassy homogeneous structure of the fibrinogen with no apparent irritation. The nerve sheath shows a normal growth. Note the absence of any foreign body reaction in the tissue.

small fragments of gray tissue said to be removed from the sheath of the sciatic nerve.

On microscopic examination the fragments were seen to consist of dense fibrous connective tissue in which were large collections of amorphous hyaline refractile granular pigment. These pigment granules were surrounded by whorls of hyperplastic fibrocytes and lymphocytes and occasional giant cells. The adjacent muscle fibers did not appear to be involved in the process.

The diagnosis was granulation tissue, nerve sheath foreign body reaction (high explosive fragment).

The pathologic report on the second operation (April 24) was as follows:

Gross. The submitted specimen consisted of a small pearly white glistening fragment of tissue removed from a nerve sheath measuring 1 by 0.5 mm. a small mass of muscle measuring 1 by 0.8 cm. and some thin sheets of fibrinogen measuring 3 by 1.5 cm. These were sectioned for microscopic study.

Microscopic. The microscopic sections taken from the fibrinogen showed glassy amorphous structure with a pronounced acidophilic staining reaction. There was very little in the way of evidence which would suggest an irritation reaction from this substance. The nerve sheath showed some clearcut fibrinogen on the surface with a few round cells and fibroblasts in the sheath but very few neutrophilic polymorphonuclear cells or other indications of irritation.

The diagnosis was fibrinogen nerve sheath fragment.

COMMENT

From the description it may be said that the fibrinogen placed around the sciatic nerve on March 23 gave little evidence of tissue irritation. A small section of nerve sheath revealed evidence of growth of a rather normal nature. There was no evidence of any foreign body reaction in the usual sense of the word and the fibrinogen showed little in the way of absorption. There was no evidence of inflammatory cells in the fibrinogen.

CONCLUSIONS

The application of this substance opens up many new possible uses in reconstructive surgery, especially in neurosurgery and tendon repair work. The microscopic sections of the nerve sheath and fibrinogen after removal show the lack of irritation or foreign body reaction yet healing has gone on normally. This procedure may be adapted to meet other needs in reconstructive surgery.

HANDBOOK OF NUTRITION: XXIV

NUTRITION IN PREVENTIVE MEDICINE

W. H. SEBRELL, MD

Senior Surgeon, U. S. Public Health Service, Chief, Division of
Chemotherapy, National Institute of Health

BETHESDA, MD

These special articles on foods and nutrition have been prepared under the auspices of the Council on Foods and Nutrition. The opinions expressed are those of the authors and do not necessarily reflect the opinion of the Council. These articles will be published later as a Handbook of Nutrition.—ED

The prevention of malnutrition and the deficiency diseases is probably the greatest and most complex problem in public health that this country has ever had. The exact extent of physical disability, economic loss and disease directly or indirectly related to nutrition are unknown and yet there is every indication that malnutrition is very widespread. Some physicians who do not see many cases of advanced deficiency disease feel that the importance of nutrition is being overemphasized. However, in every clinic in which close observations are made and the more refined methods of diagnosis used, many unsuspected cases of malnutrition are recognized, and every study reveals the importance of mild degrees of deficiency in producing symptoms the cause of which was hitherto unrecognized. Furthermore, it is significant that almost all practicing physicians are prescribing vitamin preparations for more and more of their patients.

Even before our food supply was disturbed by the conditions incident to war, a number of surveys had all shown that a large part of our population was eating foods which failed to provide the essentials in amounts recommended for optimum nutrition. For example, a survey of the diets of more than a thousand workers in a large aircraft factory¹ revealed that more than four fifths of the diets studied fell below the amounts of certain nutrients recommended by the Food and Nutrition Board of the National Research Council.² Nutritionists who have watched workers select their lunches in cafeteria lines report that not more than half of them choose good lunches even when foods needed to provide good lunches are on the counters. It was also observed that women usually made poorer choices than men. The method of food preparation also greatly affects its food value. In a study of food as it was served³ it was shown that as much as 90 per cent of the thiamine (B_1) present in the fresh raw food was lost before the food was eaten. Keeping food hot for long periods of time is really overcooking it, and the vitamins destroyed by heat and oxidation are thus lost. The hot lunch prepared and kept hot for hours before consumption may not be as satisfactory nutritionally as a cold one.

The effect of such inadequate diets on the ability of the civilian worker to do his part in the war effort must be of serious concern to us at this time. As a nation we are not as well fed as we once believed. Physicians

and health officers must recognize that here is a whole new sphere of responsibility in the field of preventive medicine as great as or greater than the field of sanitation or control of communicable diseases.

The growing recognition of the importance of nutrition in health has gone hand in hand with the development of the science of nutrition. Most of what may be called the modern knowledge of nutrition has developed during the present century and much of it since World War I. The discovery of new vitamins, the recognition of the great physiologic importance of various mineral salts and better methods of diagnosis have made the entire world increasingly aware of the enormous amount of ill health, poor development, disease and disability due either directly or indirectly to malnutrition. An indication of the extent of the problem is given just by a survey of the fragmentary reports in the medical literature on the prevalence of the vitamin deficiency diseases.

The principal dietary deficiency diseases are nutritional edema, vitamin A deficiency, vitamin D deficiency, vitamin B_1 (thiamine) deficiency, nicotinic acid deficiency (pellagra), riboflavin deficiency (ariboflavinosis), vitamin C deficiency (scurvy) and vitamin K deficiency. These diseases occur to some extent throughout the world, although there are frequently wide variations in geographic distribution.

Although reports in many instances indicate an extensive occurrence of deficiency disease, they most probably represent only a small proportion of the cases actually occurring in the world.

NUTRITIONAL EDEMA

Nutritional edema is an invariable accompaniment of famine and rapidly disappears when the patient is given enough food of good quality. Together with the prolonged undernutrition a deficiency of protein appears to be the most important factor in the production of this syndrome, although it is recognized that strenuous exercise, exposure to cold and probably other influences are contributory.

In mild cases the edema may be confined to the lower limbs, but when it is more severe it extends to all parts of the body. It is accompanied by emaciation, muscular weakness, depression, anemia and very frequently gastrointestinal disturbances. The swollen extremities are cold and painful when touched, the pulse is slow and the blood pressure is low.

This disease is very common in prison camps and during periods of famine. It has been especially prevalent in India and in China. During the latter years of the first world war it reached epidemic proportions among the poorer classes of the civilian populations of the central European countries. In Bohemia alone 22,842 cases were listed. In the Russian famine of 1921-1922 every single surviving inhabitant of certain towns was affected. During the present nutritional crisis in Europe and in China we may be certain that the incidence of nutritional edema is extremely high although no accurate figures are as yet available.

VITAMIN A

Vitamin A deficiency is manifested in human beings by lesions found chiefly in the epithelial structures. The most readily recognized symptoms are those of the severe deficiency states. Xerophthalmia is associated with atrophy of the paraocular glands, hyperkeratosis of the conjunctiva and finally involvement of the cornea leading to softening or keratomalacia and blindness.

³ Goodhart, Robert. Dietary Conditions in Industry, J. A. M. A. 121: 93 (Jan. 9) 1943.

Nyctalopia or night blindness is due to a functional failure of the retina in the proper regeneration of visual purple. The characteristic skin lesions were first recognized in Chinese soldiers in 1931.⁴ The lesions consist of epidermal hyperplasia and glandular atrophy and are represented by papular eruptions around the pilosebaceous follicles. Unlike the ocular manifestations, cutaneous eruptions occur in persons between 16 and 30 years of age and not in infants. It is common among men and 90 per cent of those showing the dermatosis have obvious ocular manifestations of vitamin A deficiency.⁵

The symptoms of milder deficiency states are more difficult to detect. Early stages of conjunctival xerosis occur which may be discovered only by biomicroscopic examination.⁶ Incipient night blindness may be demonstrable only by careful studies of dark adaptation for which a variety of photometric instruments and techniques have been introduced. Mild dermatoses resembling the

Xerophthalmia and nyctalopia have been reported from almost every part of the world. In most countries it is infrequent except under unusual circumstances. It is prevalent, however, in India,¹³ China,¹⁴ the Dutch East Indies,¹⁵ other Asiatic areas,¹⁶ British Guiana¹⁷ and sections of Africa.¹⁸ A study in South India¹⁹ in 1937 found as many as 15 per cent of 4,000 school children showing xerophthalmia and keratomalacia. In Bengal²⁰ xerophthalmia and nyctalopia were found in 9 per cent of 2,000 persons. In Tientsin, China,²¹ a survey of school children uncovered the presence of xerophthalmia in 83 per cent of certain groups. Five per cent of children admitted to a Batavia hospital²² were xerophthalmic and in Groot-Atjeh²³ it was found to be "widespread." In Ceylon²⁴ 65 per cent of the blindness was attributable to xerophthalmia, the latter being noted as "common." Of 500,000 persons in Java²⁵ about 1 per cent of blindness was found, and here too xerophthalmia was the chief cause. In

TABLE 2—Reports of Occurrence of Vitamin A Deficiency

Country and Year	Deficiency Symptom	Incidence	Groups Studied	References
NORTH AND SOUTH AMERICA				
Newfoundland, Labrador 1930-1936	Xerophthalmia, 0, dark adaptation, 8%, nyctalopia, 7%	"Probably more extensive use of controlled procedures will show that even very mild vitamin A deficiency ordinarily is rare in occidental population"	353 adults	Steven and Wald ⁴⁰
Canada (Edmonton) 1939	Dark adaptation 21%	Evidence of vitamin A deficiency	1,000 university students	Pett ⁵³
United States (Kansas) 1942	Clinical evidence	None	1,265 workmen	Schuedorf, Weber and Glendenning ⁴¹
United States (Chicago) 1941	Dark adaptation, blood levels	"Mild deficiency is rare or not detectable by these methods"	Children	Oldham, Roberts MacLennan and Schlutz ⁵³
United States (New York City) 1941	Hematoscopic slit lamp examination	4.6% showed evidence of vitamin A deficiency	Poor school children	Wiehl and Kruse ⁶
United States (California) to 1942	Clinical deficiencies	None	287 hospital patients	Krupp ⁴⁴
United States (General) to 1941	Xerophthalmia	One case in several years reported in literature		Youmans and Patton ⁴⁴
United States (General) to 1941	Nyctalopia, <i>derma</i> to 1, anatomical changes mild deficiency	Not uncommon		Youmans and Patton ⁴⁴
United States (North Carolina) 1940-1941	Clinical deficiencies Blood level at lower limits	None "Common"	Mill village community of 400	Milam ⁴⁴
United States (Texas) 1941	Dark adaptation	"High incidence" of vitamin A deficiency	900 rural people	Youmans, footnote 52 first reference
United States (Florida) 1941	Mucular conjunctivitis	21.7% had vitamin A deficiency	1,011 school children	Sandels Cate, Wilkinson and Graves ⁴²
United States (New York City) 1940	Dark adaptation	One case	144 children	Lewis and Haig ⁴⁴
United States (Tennessee) 1945	Dark adaptation	50% showed vitamin A deficiency	54 adults in Nashville	Corlette, Youmans, Frank and Corlette ⁵⁵
United States to 1947	Dark adaptation	35% showed vitamin A deficiency	Medical students	Jeghers ⁵²
United States to 1947	Dark adaptation	50% showed vitamin A deficiency	Clinic patients	Youmans, footnote 52, second reference
United States (Iowa) to 1946	Dark adaptation	26 to 70% showed vitamin A deficiency	Children	Jeans, Blanchard and Satterthwaite ⁴¹
Brazil 1932-1933	Nyctalopia	"A number of cases were observed during a period of drought"	General population	Cavalcanti ⁴⁷
British Guiana 1933	Xerophthalmia, nyctalopia	"Common"		Footnote 17
Yucatan and Labrador to 1937	Xerophthalmia, nyctalopia	"Common"	General population	Eddy and Dalldorf ⁴⁵
United States (general) to 1934	Xerophthalmia	"Rare"		Thorson J. A. M. A. 103 1433 (Nov 10) 1934
Trinidad 1941	Xerophthalmia, nyctalopia	"Rare"		Metivier ⁴⁸
EUROPE				
England 1940	Hyperkeratosis	5% had this evidence of vitamin A deficiency	General population	Pemberton ⁵⁰
England (Newcastle upon Tyne) 1938-1939	Clinical deficiencies	None	138 (poor in come group) children	Brewis and others ³⁴
France (Marseilles) 1941	Clinical deficiencies, 'Laboratory data indicating mild deficiencies'	None Widespread	Several hundred of school children and general population	Youmans ³⁰
France 1940	Total deficiency partial deficiency (Dry skin, digestive disturbance nyctalopia, irritability)	Rare Prevalent	Adults and children	Chevallier ³⁴
France to 1939	Xerophthalmia	Only 7 cases described to date	General literature	Clement and Delon ³⁵
France (Paris) 1940-1941	Xerophthalmia	Same as before (?)	In hospitals	Minoll ³⁴
France 1938	Dark adaptation	"Relatively frequently"	210 school children	Caussade and others ⁵⁷
Spain (Madrid) 1941	Nyctalopia, 2%, dermatosis, 13% blood level at or below borderline 33%	Evidences of vitamin A deficiency	106 families or 661 persons	Robinson Jauney and Grande Corlan ⁴⁴
Italy (Turin) 1939	Nyctalopia	45% showed this vitamin A deficiency	500 school children	Mathis ³⁰
Italy (Venice) 1939	Low blood levels, nyctalopia	Frequent incidence of these vitamin A deficiencies		Bretti and Tria ⁴⁰
Italy (Venice) 1939	Nyctalopia	"Common" occurrence of this vitamin A deficiency	Children	Tria ⁴⁰
Czechoslovakia (Prague) 1938	Clinical deficiencies	"No serious deficiency (vitamin A) but a slight lack of the vitamin was indicated by dry affections of the skin and nyctalopia"	Replies to 1 218 questionnaires sent to health officers	Charvat ⁴²
Sweden (Djuroholm) 1939	Dark adaptation	28% showed this vitamin A deficiency	67 school children	Abramson and Ørgaard ⁴³
Finland (Helsinki) 1940	Dark adaptation	29% showed this vitamin A deficiency	71 persons	Nylund ⁵⁹

TABLE 2—*Reports of Occurrence of Vitamin A Deficiency—Continued*

Country and Year	Deficiency Symptom	Incidence	Groups Studied	References
EUROPE—Continued				
Finland (Helsinki) 1938-1940	Dark adaptation	16% showed this vitamin A deficiency	137 persons	Simola and Sakela ²⁹
Denmark (Copenhagen) 1937	Dark adaptation	24% uncommon	300 hospital patients	Mowinkel Reistrup and Reiter ³³
Denmark (Copenhagen) 1935	Dark adaptation	71% showed this vitamin A deficiency	63 children	Frandsen ³⁶
Germany (Posen) 1941	Dark adaptation	None	173 persons	Widenbauer ³⁰
Germany (Halle) 1939	Nyctalopia	17% showed this vitamin A deficiency	718 persons	von Drigalski and others ⁴³
Sweden Norway Finland Czechoslovakia Yugoslavia 1939	Nyctalopia dermatitis	Frequently reported	Rural population	Bull Health Organ ⁴¹
Egypt (Cairo) 1935	Xerosis of conjunctiva and cornea nyctalopia	0.4% 0.0%	Patients in general ophthalmologic hospital	Giza Memorial ³¹
Tanganyika Territory 1939	Dark adaptation, nyctalopia 10%	98% showed this vitamin A deficiency	94 native patients and convicts' school boys	Mckenzie ³²
Uganda (Teso) 1935	Xerophthalmia phrynodermia	700 cases 30% in children 82% in adults	1112 persons	Loewenthal ³⁰
Union of South Africa 194	Keratomalacia Bitot's spots Phrynodermia	None Considerable number	841 children	Brock and Latzky ³²
Falkland Islands 1937	Xerophthalmia	None		Annual report ³⁵
ASIA				
India (Calcutta) 1941	Dark adaptation nyctalopia	6% of these vitamin A deficiencies	138 persons	Roy and Bauergee ⁴¹
India (Calcutta) 1941	Lesions from nyctalopia to xerophthalmia	5%	1400 persons in eye infirmary	Kirwan Sen and Biswas ¹³
India (Bengal) 1941	Xerophthalmia nyctalopia	9%	2000 persons	Biswas ⁹
India (Bengal) 1941	Dark adaptation	25% were below standard	391 school boys	Basu and De ⁴¹
India (general) to 1937	Xerophthalmia nyctalopia	Common	General population	Eddy and Dalldorf ⁴⁵
India (Kashmir) 1939	Phrynodermia	10% showed this vitamin A deficiency	Children	Nicholls and Nimalasuriya ⁴⁹
South India 1937	Xerophthalmia keratomalacia	Up to 15%	4000 school children	League of Nations ¹⁰
China to 1937	Xerophthalmia, nyctalopia	Common	General population	Eddy and Dalldorf ⁴⁵
China (Tientsin) 1939-1930	Xerophthalmia	Eye clinic patients 6% charity boarding schools 83% poor vernacular schools 29% upper class schools 3% mental asylums 44% mental asylums (Europe) 2%		Nicholls ⁴¹
Malaya (Singapore) 1935	Xerophthalmia	Not uncommon	Children	Malaya Journal ¹⁶
Dutch East Indies (Batavia) 1935-1940	Xerophthalmia	5%	Children admitted to hospital	De Haas and others ²²
Dutch East Indies (Groot Atjeh) 1937	Xerophthalmia	Widespread		Gomperts ²³
Dutch East Indies (Batavia) 1937-1939	Dark adaptation	60 to 80% showed this vitamin A deficiency	430 persons	Gorter ⁴²
Dutch East Indies 1938	Xerophthalmia	13%	3000 children under 15 years	Hadikoesoemo ¹⁸
Dutch East Indies 1937	Xerophthalmia keratomalacia nyctalopia	Common		League of Nations Conference ¹⁵
China 1937	Xerophthalmia keratomalacia	Common		
British Solomon Islands 1937	As above	Common		
New Hebrides (Condominium) 1937	As above	Unknown		
Tonga Island 1937	As above	Exists		
Fiji Islands 1937	As above	Almost complete absence		
Dutch East Indies (W. Java) 1939	Xerophthalmia	About 1% blindness of which xerophthalmia is chief cause	500000 persons	Tjissen ¹⁵
Dutch East Indies (Sumatra) 1939	Xerophthalmia (mild and severe)	88% to 2 years 51-61% 2-15 years 20% 15 years	3684 children	Maas ¹⁶
Ceylon (Southern) 1939	Phrynodermia Bitot's spots	21% 56%	9% children 1497 children	Nicholls and Nimalasuriya ⁴⁹
Ceylon (Northern) Ceylon 1937	Bitot's spots Xerophthalmia	Less than above 6% of blindness caused by xerophthalmia		Nicholls and Nimalasuriya ⁴⁹
Ceylon 1937	Xerophthalmia	Common	Prisoners	Ceylon Sectional Paper ¹⁷
Philippine Islands 1939	Xerophthalmia	1%	867 persons	Ubaldo and de Campo ²⁷
Philippine Islands 1937-1937	Keratomalacia	47 cases noted	Pediatric service of General Hospital in children—5 yrs	Tupas and Pacache ¹⁴

nia and nyctalopia were reported as "common" in the British Solomon Islands,²⁸ as "unknown" in the New Hebrides Condominium,²⁹ as "existing" in the Tonga Islands²⁸ and "almost completely absent" in the Fiji Islands.²⁸

Reports²⁹ from Tanganyika Territory in 1939 showed 10 per cent of the school boys to be suffering from night blindness. In Leso, Uganda,³⁰ a 30 per cent incidence of xerophthalmia was found among children in a group of 1,112 persons of all ages. In Cairo, Egypt,³¹ only 0.2 per cent of persons attending a general ophthalmologic hospital were nyctalopic, and 0.4 per cent showed xerosis of the conjunctiva and cornea. No cases were found in a thorough 1942 survey of 841 children in the Union of South Africa³² and none were noted in the Falkland Islands.³³

In Europe, xerophthalmia is uncommon.³⁴ Up to 1939 only 7 cases had been reported in the French medical literature,³⁵ and reports up to 1941³⁶ failed to add any further cases. Under unusual circumstances the disease appeared in epidemic form, as in Denmark³⁷ during World War I, when dairy products were replaced in the diet by fats lacking in vitamin A. A recent survey of 106 families including 561 persons in Madrid, Spain,³⁸ uncovered only 2 per cent with nyctalopia. In Italy, however, the incidence is reported to be much higher. In Turin in 1939³⁹ 45 per cent of 500 school children had night blindness, and it was also found to be common in Venice.⁴⁰ A study of rural populations⁴¹ revealed that nyctalopia and dermatosis were "frequently reported" from Sweden, Norway, Finland, Czechoslovakia and Yugoslavia. A year earlier, in 1938, a report⁴² from Prague based on a questionnaire survey found no serious deficiencies, although dermatoses and nyctalopia were noted. In Halle, Germany,⁴³ in 1939 17 per cent of 218 persons were found to be night blind.

In the United States¹ xerophthalmia, keratomalacia and nyctalopia due to vitamin A deficiency are rarities. In Yucatan⁴⁵ and British Guiana⁴⁷ they are reported as "common." A recent study in Newfoundland and Labrador⁴⁶ uncovered no cases of xerophthalmia and only 3 per cent of night blindness among 353 adults. In Brazil⁴⁷ a number of cases of nyctalopia were noted

during a period of drought. The conditions were reported from Trinidad⁴⁸ as of "rare" occurrence.

The severe dermatoses of vitamin A deficiency are found in the same geographic distribution as the advanced ocular manifestations. Reports from China⁴⁹ and other countries⁴⁹ indicate the incidence of this symptom to be as high as or higher than that of ocular symptoms. The occurrence of mild dermatoses as evidence of low grade vitamin A deficiency has been reported widely. Five per cent of a general population group in England⁵⁰ in 1940 showed such a hyperkeratosis, and 13 per cent of a similar group in Madrid, Spain,³⁸ in 1941 had such lesions. It has been frequently reported from the Scandinavian countries,⁵¹ central Europe,⁵¹ Asia⁴⁹ and South Africa.³²

The failure of the eye to adapt properly to darkness has been reported as a mild vitamin A deficiency symptom and has been subjected to refined biophotometric measurement. Reports of such studies have been at variance as the result of the multitude of techniques and instruments employed, the failure to consider other etiologic factors of dysadaptation and the unavailability of universally accepted criteria of subclinical vitamin A deficiency disease to serve as standards.

A high incidence of dark dysadaptation has been reported widely in the United States⁵² and throughout the world.⁵³ Among 120 Iowa school children⁵⁴ almost 20 per cent showed abnormal adaptation in the winter and 5 per cent in the fall. Of 54 adults studied in Tennessee⁵⁵ 27 had subnormal abilities to adapt to darkness. In Copenhagen⁵⁶ 46 of 65 healthy school children showed this impairment. Similar findings have been reported from France,⁵⁷ Sweden,⁵⁸ Finland,⁵⁹ Germany,⁶⁰ India,⁶¹ Africa²⁹ and the Dutch East Indies.⁶² However, reports indicating a very low incidence of dark dysadaptation are also available. A study of Chicago children⁶³ in 1942, augmented by determinations of vitamin A blood levels, led to the conclusion that "mild vitamin A deficiency is rare or not detectable by these methods." Only 1 case of dark dysadaptation⁶⁴ was found among 144 New York City school children.

Very mild degrees of conjunctival xerosis recently have been attributed to a deficiency of vitamin A. By means of a biomicroscopic slit lamp, 86.6 per cent⁶ of poor school children in New York City were found to exhibit such lesions. A follicular conjunctivitis also

thought to be etiologically related to vitamin A deficiency was present in 21.7 per cent of 1,041 Florida⁶⁵ school children

VITAMIN D DEFICIENCY

Nutritional diseases due to deficiencies of vitamin D and calcium may be divided into three important categories, namely rickets, osteomalacia and tetany. The three conditions, though usually separated for descriptive purposes, have ramifications that make it difficult to separate them completely.

and severity in various localities. The greatest local prevalences were found in larger cities where poor housing, inadequate diets and limited exposure to sunshine exists. The disease has been reported to be, as a rule, most prevalent in the north temperate zone and least prevalent in the tropical and subtropical areas.

An incidence of 75 to 97.6 per cent of children having symptoms of rickets has been reported in certain areas of the United States,⁶⁷ in Germany,⁶⁸ Italy,⁶⁹ Sweden,⁷⁰ the British Isles⁷¹ and Egypt,⁷² in from 25 to 75 per

TABLE 3—Occurrence of Rickets

Rickets—Neff⁶⁶ defines rickets as a "nutritional and metabolic disease of the first two years of life, the chief characteristic of which is a failure to appropriate or retain calcium in the bones, which become soft and deformed."

The existence of rickets has been demonstrated throughout most of the world varying in its frequency

cent of children in Switzerland,⁷³ in the United States,⁷⁴ the British Isles⁷¹ and Argentina,⁷⁵ among nomad Laplanders⁷⁶ in the cantons of Colmar and Andolsheim,⁷⁷ in Norway⁷⁸ and Germany⁷⁹ and from 0 to

25 per cent in localities in China,⁸⁰ the Panama Canal Zone,⁸¹ Puerto Rico,⁸¹ Palestine,⁸² Uruguay,⁸¹ Africa,⁸¹ France,⁸³ Italy,⁸⁴ Ecuador,⁸⁵ Haiti,⁸⁶ Honduras⁸⁰ and in Peru⁸⁰

The disease in itself is rarely fatal, but intercurrent infections may develop that are difficult to control, owing to the low resistance of the individual. The Bureau of the Census⁹¹ for the United States lists rickets as a cause of death in each of nine years from 1933 through 1941 as ranging from 339 to 139. In England and Wales⁹² it was listed as the cause of death for eleven years from 1928 through 1938 as ranging from 493 to 121. There were 554 deaths in Italy in 1937,⁹³ 129 in Colombo, Ceylon, in 1939,⁹⁴ 21 deaths of 57 patients with rickets admitted to all hospitals in the Malaya States in 1938⁹⁵ and 170 deaths of 195 patients with rickets in hospitals in Chile in 1942.⁹⁶

Osteomalacia—This is a nutritional disease of adults resulting from deficiency of vitamin D and the failure of utilization of calcium. It is characterized by pro-

Although osteomalacia has become an exceptional disorder among peoples living under modern civilizations, there are still large areas where it constitutes a medical problem. It was reported to be widely distributed in India,⁹⁷ in the province of Shansi, China,⁹⁸ in the province of Toyama, Japan,⁹⁹ and in an isolated district of Bosnia,¹⁰⁰ where 3,510 cases were seen in the twelve years previous to 1910. The disease is most frequently found in India among women of the upper and middle classes who practice seclusion or purdah after marriage. It is seldom found among the lower classes who have to work outdoors.

This disease and rickets have the same etiologic factors, viz. vitamin D deficiency and disturbance of calcium metabolism, also no sharp distinction can be drawn between late or adult rickets and osteomalacia. It has been reported¹⁰¹ that among 1,000 children of well-to-do parents whose mothers observe purdah 25 per cent had rickets, whereas among 2,300 children of low caste Hindus only about 5 per cent were affected.

"War Osteopathy," or "Hunger Osteomalacia"—A nutritional disorder which was generally termed "war osteopathy" or "hunger osteomalacia" made its appearance among the peoples of central Europe shortly after World War I. It was common in Austria, Germany and Poland. This disorder was characterized by pains in the back, groins and legs, by a somewhat characteristic gait, by difficulty in climbing stairs and by some tenderness of the bones. The age and sex distribution was peculiar. Beninde¹⁰² stated that there was pronounced susceptibility of adolescents, mainly males, almost no cases occurred between the ages of 20 and 35, whereas the high incidence was in the period from 40 to 60 years, confined almost entirely to women. Hess¹⁰³ states that the condition "developed to a degree and extent such as had never been experienced in the history of medicine. Marked deformities of the spine and the extremities, multiple fractures, and functional disabilities by the thousand, were observed throughout the land." He reasons that from the very close resemblance between this condition and the classic osteomalacia it would seem of advantage to class them as one and the same disorder.

Tetany—This is a syndrome manifested by sharp flexion of the wrists and ankle joints, muscle twitchings, cramps and convulsions. It is due to abnormal calcium and phosphorus metabolism. It may be associated with several conditions, but consideration here is given only to its association with vitamin D deficiency in relation to rickets and osteomalacia. As in rickets, the peak of the incidence of tetany is in late winter and early spring.¹⁰⁴

Tetany has often been noted in cases of rickets and osteomalacia. In one report¹⁰⁵ it was recorded that one fifth of the cases of rickets and one third of their cases of osteomalacia showed signs of tetany. In another report¹⁰⁶ it was stated that 30 of 63 patients with

rickets had tetany, while in another¹⁰⁰ it was noted that tetany occurred in 338 of 3,510 cases of osteomalacia seen in Boston.

Tetany in rickets may be the immediate cause of death. This comes about either by the result of heart failure following spastic contraction of the heart muscle or by respiratory failure of cerebral origin. Happily this result is infrequent, as there are many therapeutic measures available for rapidly controlling the convulsive seizures. Some cases, however, resist all measures.

Reports in recent years on incidence of tetany in various localities are limited as a rule to individual case reports. Snelling and Brown¹⁰¹ reported 32 cases in 1928 and 28 in 1935 at the Hospital for Sick Children in Toronto, Canada. Hennig¹⁰² observed 79 cases of manifest tetany in central Europe from 1933 to 1937.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING STATEMENT

ALSTIN E SMITH M.D. Secretary

THE USE OF VITAMIN D IN THE TREATMENT OF REFRACTORY RICKETS

The Council has given consideration to the use of relatively massive doses of vitamin D in the treatment of refractory rickets and has accepted at least one preparation designed for such use. As a result of this consideration and acceptance the Council has voted to revise the statement on vitamin D (New and Nonofficial Remedies, 1943, pages 582-583) by the addition of the following paragraph:

Another suggested use of massive doses of vitamin D is in the treatment of refractory rickets, that is, occasional cases of rickets which do not respond to treatment with the usual dosages or even much larger dosages of vitamin D. In some of these cases the rickets is due to a disturbance of the acid base balance and has been successfully treated by administration of sodium bicarbonate or a sodium citrate-citric acid mixture. Massive doses of vitamin D have proved effective in the control in others. The quantity of vitamin D needed may be so large that it borders on the dosages of vitamin D that are definitely toxic, and such treatment should not be undertaken without first exploring other possibilities or without careful observation for signs of toxicity. Some investigators believe it desirable to examine the urine daily for calcium casts, albumin and red blood cells while the maintenance dose is being established. Others believe less frequent examination is necessary. After the dose is established weekly examination, using the Sulkowitch test for excessive excretion of calcium is sufficient. The blood should be examined weekly or oftener to avoid a rise of calcium above 12 mg. per hundred cubic centimeters if the dosage exceeds 20,000 units daily for the infant or 50,000 units for a child. If anorexia or nausea should appear the child must be brought promptly to the attention of the physician and vitamin D administration should be discontinued. When the maintenance dose has been established operative procedures to correct rachitic deformities may precipitate a temporary state of toxicity and the blood levels of calcium must be watched closely.

The Council voted further to revise the Allowable Claims¹⁰³ which appear on pages 583-584 by the addition of the following sentence to claim 6, which appears on page 584:

If representations are made for use of massive doses of vitamin D in the treatment of refractory rickets they must be accompanied by adequate precautions with respect to the danger of toxic effects and how they can be avoided.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ALSTIN E SMITH M.D., Secretary

VITAMIN B COMPLEX PREPARATIONS (See New and Nonofficial Remedies, 1943, p. 588)

The following products have been accepted

ABBOTT LABORATORIES, NORTH CHICAGO, ILL.

Brewers' Yeast Powder Fortified with Riboflavin and Nicotinic Acid. Contains dried brewers' yeast (*Saccharomyces cerevisiae*), debitterized, fortified with crystalline riboflavin and nicotinic acid to contain in each gram vitamin B₁ 50 U S P units (0.15 mg.), riboflavin 0.3 mg. and nicotinic acid 15 mg. Daily prophylactic dose for infants, $\frac{1}{2}$ level teaspoon, children 1 to 6 years old, 1 level teaspoon, children 6 to 12 years old, $1\frac{1}{2}$ level teaspoons, older children and adults, 2 level teaspoons mixed with water, milk or fruit juices.

Brewers' Yeast Tablets, 0.4 Gm. (6 grains), Fortified with Riboflavin and Nicotinic Acid. Each tablet contains Abbott's Brewers' Yeast Powder Fortified with Riboflavin and Nicotinic Acid 0.4 Gm. providing in each tablet vitamin B₁ 20 U S P units (0.06 mg.), riboflavin 0.12 mg., nicotinic acid 0.6 mg. Average daily dose, as a supplement to the diet for children 6 to 12 years old, 6 tablets; older children and adults 9 tablets, therapeutic doses must be determined for each patient.

DIGITALIS* (See New and Nonofficial Remedies 1943, p. 289)

The following dosage forms have been accepted

PITMAN-MOORE COMPANY, INDIANAPOLIS

Tablets Digitalis 32 mg. ($\frac{1}{2}$ grain) ($\frac{1}{2}$ U S P unit), 65 mg. (1 grain) ($\frac{2}{3}$ U S P unit) and 0.1 Gm. ($1\frac{1}{2}$ grains) (1 U S P unit) (keratin coated)

Pulvo-Caps Digitalis 0.1 Gm. ($1\frac{1}{2}$ grains) (1 U S P unit) and 65 mg. (1 grain) ($\frac{2}{3}$ U S P unit)

Tincture Digitalis Four fluidounces and 1 pint bottles

OLEOVITAMIN A (See New and Nonofficial Remedies, 1943 p. 587)

The following dosage form has been accepted

INTERNATIONAL VITAMIN SALES CORP., NEW YORK

Oleo Vitamin A Capsules. Each capsule contains 25,000 U S P units of vitamin A derived from fish liver oils

PROCAINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1943, p. 82)

The following dosage forms have been accepted

E. S. MILLER LABORATORIES, INC., LOS ANGELES

Sterile Solution Procaine Hydrochloride 1% W/V 30 cc., 50 cc. and 100 cc. vials and 2 cc. and 5 cc. ampuls Preserved with 0.5 per cent chlorobutanol

Sterile Solution Procaine Hydrochloride 2% W/V 30 cc., 50 cc. and 100 cc. vials and 2 cc. and 5 cc. ampuls Preserved with 0.5 per cent chlorobutanol

RABIES VACCINE CHLOROFORM KILLED (See New and Nonofficial Remedies 1943 p. 543)

The following dosage form has been accepted

THE GILLILAND LABORATORIES, INC., MARIETTA, PA.

Rabies Vaccine (Chloroform Killed Virus) 0.5 cc. vials packaged in units of seven and fourteen vials

SULFADIAZINE (See New and Nonofficial Remedies, 1943 p. 169)

The following dosage forms have been accepted

E. R. SQUIBB & SONS, NEW YORK

Tablets Sulfadiazine 0.5 Gm.

Sulfadiazine Powder (Sterilized) 5 Gm. vial

SULFADIAZINE SODIUM (See New and Nonofficial Remedies 1943 p. 188)

The following dosage forms have been accepted

E. R. SQUIBB & SONS, NEW YORK

Sulfadiazine Sodium Powder (Sterilized) 5 Gm. vial

Sulfadiazine Sodium Powder (Nonsterilized) 50 Gm. bottle

INFLUENZA RECEPTOLYSIN

New facts regarding the mechanism of virus infections of the respiratory epithelium have resulted from studies of virus hemagglutinins recently reported by Hirst¹ of the International Health Division, Rockefeller Foundation. Two years ago Hirst noted that influenza virus grown in the allantoic fluid of chick embryos would agglutinate adult fowl erythrocytes. This hemagglutinin could be used as a reliable quantitative index of the mouse infectious titer of influenza virus and for the titration of anti-influenza serums. The observation was promptly confirmed by other investigators,² who reported evidence that the influenza virus is actually adsorbed on fowl erythrocytes, from which it can be partially or wholly recovered by elution.

Quantitative studies of the rate and completeness of this virus adsorption yielded surprising results. For example, Hirst found that addition of the Lee strain of influenza B virus to a 1.5 per cent suspension of chicken erythrocytes caused the titer of the free, or uncombined, virus to fall from 128 units to less than 4 units by the end of ten minutes, a 94 per cent adsorption of the virus on the red blood corpuscles. This adsorption, however, did not result in a permanent chemical union between virus and erythrocytes, release of the adsorbed virus was noted within twenty minutes, increasing to a measurable amount by the end of two hours. There was no demonstrable multiplication of the virus in the blood suspension to account for this release.

The released virus was apparently unaltered as a result of its previous adsorption on the erythrocytes.

¹ Hirst, G. K. The Agglutination of Red Cells by Allantoic Fluid of Chick Embryos Infected with Influenza Virus, *Science* **94**: 22 (July 4) 1941, The Quantitative Determination of Influenza Virus and Antibodies by Means of Red Cell Agglutination, *J. Exper. Med.* **75**: 49 (Jan.) 1942, Adsorption of Influenza Hemagglutinins and Virus by Red Blood Cells, *ibid.* **76**: 195 (Aug.) 1942.
² McClelland, Laurella, and Hare, Ronald. The Adsorption of Influenza Virus by Red Cells and a New In Vitro Method of Measuring Antibodies for Influenza Virus, *Canad. Pub. Health J.* **32**: 530 (Oct.) 1941.

The blood cells, however, were definitely changed, as shown by their acquired insusceptibility to subsequent agglutination with influenza virus. To account for this insusceptibility, Hirst postulated the existence of specific haptens or receptor materials on the fowl erythrocytes, which he had reason to believe were complex polysaccharides. He assumed further that this receptor substance is destroyed by enzymes (or functions) of the influenza virus. Release of the virus was therefore pictured as a result of receptor hydrolysis, the resulting dehaptenized erythrocytes being incapable of adsorbing influenza virus. This is essentially a renaissance of the original Pasteur exhaustion theory of acquired immunity.

It seemed likely to Hirst³ that this in vitro adsorption and release of influenza virus might have its counterpart in the reactions between influenza virus and respiratory epithelium. He therefore repeated the experiments using mouse, rabbit and ferret lungs in place of fowl erythrocytes. The lungs were first perfused free from blood and then suspended in an Erlenmeyer flask with a side arm by means of which the external pressure could be increased or decreased. Virus infected allantoic fluid was introduced into the trachea of the suspended lungs, and the lungs were alternately expanded and compressed to insure uniform mixture. Samples of the allantoic fluid were removed at intervals and titrated for hemagglutinins and for their lethal effects on mice. These titrations showed an extremely rapid adsorption of the virus on the respiratory epithelium. With the PR8 virus less than 1 per cent remained unabsorbed after five minutes of the simulated respiratory movements. This was followed by a fairly rapid release of the virus, the original titer of the allantoic fluid being restored almost quantitatively in from two to five hours. As in previous tests with red blood cells, the rapidity of the adsorption and subsequent release of the virus varied with different viral strains. Heat inactivated and formaldehyde inactivated influenza viruses were also adsorbed and at the same rate, but there was no evidence of their subsequent release, presumably owing to inactivation of their enzymic function.

In order to test possible clinical applications of these observations, the tests were repeated on the intact lungs of living ferrets. In the case of ferrets killed at stated intervals after intratracheal inoculation, adsorption of the virus had taken place in the viable lung in much the same way as in the isolated blood free lungs. The adsorbed virus, however, remains permanently adsorbed on the epithelial cells of the living lung.

³ Hirst, G. K. Adsorption of Influenza Virus on Cells of the Respiratory Tract, *J. Exper. Med.* **78**: 99 (Aug.) 1943.

release being still absent at the end of eight hours. A slight apparent release of one virus was noted at the end of twenty-four hours, presumably because of multiplication.

Assuming that virus release is due to enzymic hydrolysis of the specific receptor substance, one might be tempted to postulate that this nonrelease is due to enzyme inhibitors in the living tissue cells or adjacent blood plasma. Hirst, however, is inclined to attribute it to aggressive growth of the attached virus under natural conditions of infection, destruction of the specific receptor substance being a necessary preliminary to parasitism on or within susceptible tissue cells.

Aside from its theoretical interest, isolation and identification of the postulated specific receptor substance have numerous suggestive practical applications. Hirst's work, therefore, may well lead to new methods of influenza prophylaxis and therapy. The work is being continued in the International Health Laboratory.

THE INTERNATIONAL RED CROSS IN TIME OF WAR

The International Red Cross was born of war and still serves most actively in wartime. The International or Geneva Red Cross movement rests on the foundation of the individual national organizations even though these vary widely in structure and importance in different countries. Since 1928 the International Red Cross has been a three headed organization which includes the national societies of the Red Cross, the International Committee and the League of the Societies of the Red Cross.¹

During the war of 1870 the International Committee assumed for the first time the assistance to prisoners of war and created an agency for prisoners at Basle. Later this agency was removed to Geneva. Past experiences were reviewed in 1929, this resulted in the adoption of the revised convention of Geneva in that year regarding the treatment of prisoners of war. This convention was ratified by most countries except Finland, Japan, Russia and certain countries of Latin America.

The principal features of this code relate to the visiting of camps for prisoners of war by delegates of the International Committee. The official delegates may consult with trusted prisoners ("hommes de confiance") who have been selected by their comrades and who represent them. These visits to camps make it possible for the delegates of the committee to request the camp authorities for improvements, they allow for the intervention of the International Committee itself

By reciprocity these visits permit equal improvements to be made in the conditions of prisoners of war held by the other side.

The Central Agency for Prisoners in Geneva is concerned not only with prisoners of war but with all categories of war victims including wounded and sick, civilian internees, military internees in neutral countries, refugees in their own countries and civilians separated from their families by hostilities. This agency is consequently a vast organization with four big buildings in Geneva and 3,500 workers, it has received over 19 million letters and telegrams and has dispatched some 20 million. Some 60 thousand letters are received by this agency each day.

Cards of notice of capture are worded by the prisoners themselves. The prisoners are permitted to send these cards to their families and at the same time to the central agency after they reach camp. The agency also carries through special inquiries for prisoners, notably when sick, or for those who have disappeared. These inquiries allow more complete information to be transmitted to the families. Another function of the International Committee is to arrange for the repatriation of the severely wounded. This ordinarily involves an exchange, usually through a neutral country. The interests of civilian internees and civilians in general are also represented by the International Committee. The committee collaborates with the diplomatic representatives of the powers, aids in problems of transportation, reports all violations of the conventions and is sometimes called on to enter into relations with governments, National Red Cross Societies or in unusual judicial situations.

A monthly journal in French records much of the current work of the International Red Cross. Of particular interest to Americans are the reports of visits to military prison camps and civilian internees in Japan proper and in such places as Shanghai and Hong Kong. Japan, although not a signatory of the Geneva Convention, previously indicated its intention of complying with its provisions. In most camps visited, conditions for both military personnel and civilians appear to be satisfactory. One recent report concerning the Stanley Camp for interned civilians at Hong Kong makes the somewhat enigmatic statement that the composition of rations has been recently improved. Reports on Japanese camps for Chinese and vice versa and on Russian camps for Axis prisoners and the reverse are missing.

Altogether the International Red Cross exerts a powerful force toward the amelioration of the effects of war and represents an extension of the endeavors of the medical profession throughout its long history.

Current Comment

WAR SURGERY IN THE MIDDLE EAST

During the last nine months of 1942, 3,279 battle casualties were admitted to one military hospital on the lines of communication in the Middle East. Because of the enemy's rapid advance to El Alamein the arrival of wounded was so rapid that the hospital had to act as a casualty clearing station rather than as a base hospital. The mortality rate for the 300 casualties from Tobruk was 3 per cent and for the 500 casualties from the second battle of El Alamein it was 10 per cent. The mortality rate for 2,679 casualties from the first battle of El Alamein, when the hospital acted as a casualty clearing station, was only 1.3 per cent. The high mortality rate for the casualties from Tobruk and from the second battle of El Alamein is due to the fact that seriously ill patients were sent to the hospital. The figure 1.3 per cent is approximately accurate for most casualty clearing stations. In analyzing the results, Lieut Col R K Debenham¹ emphasizes that all of the wounds dealt with were a result of fighting in dry sandy desert that the amount of clothing worn was very small so that only rarely was clothing found in a wound, and that sulfanilamide was used prophylactically. As a routine 10 Gm was dusted into the wound and another 10 Gm after operation, 5 tablets (2.5 Gm) were given by mouth at 6 a.m. and 6 p.m. daily for four days. The good results obtained in abdominal cases, particularly in those with bowel perforation, were due to early operation. Of the 11 patients with bowel perforation, the 9 who recovered were operated on in forward areas and were kept there from five to sixteen days, the cardinal points seem to be early operation, late evacuation, intravenous saline drip, continuous gastric suction and sulfadiazine. This is difficult with mobile warfare but was possible when the line of battle was static. The worst cases of burns came from fighting in tanks. Because facilities for preliminary cleansing were not obtainable, tanning was discarded in favor of cleansing and powdering the area with sulfanilamide and dressing with petrolatum gauze. Patients traveled best with plenty of padding, and for wounds of limbs a light, well padded plaster of paris cast was definitely beneficial. In the early stages intravenous plasma or serum was considered essential. Blood transfusions were used for secondary anemia a week or ten days later. Patients with severe burns traveled badly, even up to two weeks after burning. After a long journey they arrived toxic and ill. It is easy to put too much sulfanilamide powder on the burns, especially in severe cases, as sulfanilamide is readily absorbed from burned areas and gives rise to profound toxemia. Blood and plasma or serum transfusions were used for shock, for burns and during

convalescence when the hemoglobin fell below 60 per cent. Gas gangrene has been rare and gas infection uncommon. No case of tetanus has been seen. Among the "don'ts" to be observed are listed

Don't suture wounds. Don't suture amputation stumps.
Don't amputate at the site of election, go below it.
Don't use packing except to stop hemorrhage.
Don't use drainage tubing.
Don't use unpadded plasters.
Don't forget to give morphine before a long bumpy journey.
Don't forget to give plenty of fluids by mouth.
Don't forget that the ligature of a main vessel should be prominently recorded on the field medical card and underlined.

The salient features of war surgery in the Middle East are based on the principles which have been in the process of evolution since the beginning of the war. They are summarized as follows: organized resuscitation and the use of local and general sulfanilamide, thorough immobilization, conservative surgery and wound trimming instead of wound excision, avoidance of tension around wounds and provision of a good blood supply in damaged limbs, and the necessity to adapt and improvise articles to fulfil functions for which they were not intended.

PERSONAL LIABILITY TO ACCIDENT

The toll from accidents in 1942 was 93,000 killed and 9,200,000 injured. According to the National Safety Council² two out of three industrial accidents—and many of the nonindustrial ones—have personal as well as mechanical causes. The importance of identifying accident-prone persons preferably before the occurrence of the accident is hence obvious. Dunbar³ discusses a series of tests based on educational and vocational histories, family relations and information from personal observations, especially with regard to interests and addictions, attitude toward authority and impulsive behavior, by means of which it is believed that accident-prone persons can be identified with reasonable accuracy. The major sphere of difficulty of the accident-prone person appears to lie in the frequency of conflict with authority and the means by which such conflict is resolved. The tendency toward impulsive behavior, on which evidence may be gathered both from past history and from observation of actual behavior under stress, is also of importance, Dunbar says. If the validity of the proposed methods of selecting accident-prone persons can be confirmed—and ample opportunities are available to do so both in industry and in military life now—much may be learned concerning the possibilities for reeducation and the selection of persons for exclusion from certain occupations. Under the stress of war the available techniques can be more readily evaluated just as the problem of accident prevention becomes even more than usually acute.

MEDICINE AND THE WAR

In this section of The Journal each week will appear official notices by the Committee on War Participation of the American Medical Association, announcements by the Surgeon Generals of the Army, Navy and Public Health Service, and other governmental agencies dealing with medicine and the war, and such other information and announcements as will be useful to the medical profession

ARMY

EXAMINATION DATES FOR CANDIDATES FOR MEDICAL CORPS, REGULAR ARMY

The War Department announced on September 7 that examinations for the purpose of qualifying candidates for appointment as first lieutenants in the Medical Corps, Regular Army, to fill vacancies occurring during the fiscal year 1945 will be held on Jan 24 through Jan 27, 1944. The examinations are open to all male citizens of the United States who are graduates of acceptable medical schools in the United States and Canada, who have completed one year's internship in an approved hospital and who will not be over 32 years of age at the time it will be possible to tender a commission. The examinations will be conducted by boards of medical department officers and will consist of a physical examination, a written examination in professional subjects and a determination of the candidate's adaptability for military service. Candidates who fail a first examination will not be permitted to take more than one subsequent examination.

Full information and application blanks will be furnished on request by the Adjutant General, War Department Washington 25, D. C. Applications from candidates in the continental limits of the United States received after Jan 7, 1944 will not be considered.

TWENTY-FOURTH CLASS OF MEDICAL ADMINISTRATIVE CORPS OFFICERS

The twenty-fourth class of Medical Administrative Corps Officers at the Officer Candidate School, Camp Berkeley, Texas, graduated on September 16. This class was the last to graduate under the twelve week training schedule. Future classes will complete a sixteen week program which does not include any more material but emphasizes the physical aspects of training with more field exercises and bivouacs. The graduation address was delivered by Brig Gen Roy C Heflebower, school commandant, and the oath of office was administered by Major Miles G Ball M. A. C. executive officer.

ENLISTED WACS OFFERED OPPORTUNITY TO BECOME PHYSICAL THERAPY AIDES

The War Department announced on September 13 that qualified enlisted members of the Women's Army Corps will be given an opportunity to become physical therapy aides, with the relative rank of second lieutenant serving in the Medical Department of the Army of the United States. The training courses in physical therapy will begin in October under the direction of the Surgeon General who will select the WAC personnel to be trained. On successful completion of the study and three months practice, the Wacs will be discharged from the Women's Army Corps and will be appointed as physical therapy aides. To be eligible for this course applicants must be under 44 years of age, must have completed the WAC basic training and must have a degree in physical education or two years of college study emphasizing the biologic sciences. Successful applicants will receive six months of training in physical therapy in classes at universities and hospitals. On completion of those studies they will be assigned to selected army hospitals for practical experience in the treatment of wounded soldiers. The first groups selected will be sent to Leland Stanford Uni-

versity at Palo Alto, Calif, the University of Wisconsin at Madison, and the D. T. Watson School of Physical Therapy at the University of Pittsburgh. They will be trained at government expense and be quartered on or near the university campuses. Later it is expected that Walter Reed General Hospital, Washington, D. C. and other army general hospitals will participate in the training. Major Emma E. Vogel is the director of physical therapy aides.

MICHAEL REESE HOSPITAL UNIT IN ITALY

An army evacuation hospital built around the original Michael Reese Hospital which was formed in Chicago is reported to have landed in Italy with the American Fifth Army. The hospital was immediately set up and can handle 1,000 patients and treat every type of casualty. Hundreds of tons of equipment were landed with the unit, and the personnel includes specialists in every branch of surgery. Lieut Col Philip A. Daly of Chicago is in command of the unit, and other medical personnel are as follows:

Major Alfred E. Jones Chicago	Capt. Saul A. Mackler Chicago
Major Manuel E. Lichtenstein, Chicago	Capt. Philip M. Marcus Chicago
Major Samuel Perlman Chicago	Capt. William H. Parker Oak Park Ill.
Major Laurence M. Weinberger, Chicago	Capt. Alfred J. Platt Chicago
Capt. Harry E. Barnett Chicago	Capt. Arthur H. Schoenewetter
Capt. Richard M. Bendix Chicago	Capt. Morris J. Shapiro Chicago
Capt. David Z. Berger Chicago	Lieut. Sol Z. Shaprin Chicago
Capt. Ernest D. Bloomenthal Chicago	Lieut. Samuel H. Fraerman
Capt. Joseph A. Carbone Garv. Ind.	Lieut. Jesse G. Garber Chicago
Capt. Melvin R. Cohen Chicago	Lieut. Wilbur Gordon Chicago
Capt. Norman R. Cooperman Chicago	Lieut. Ralph R. Landes Chicago
Capt. Sol Ralph Friedlander Chicago	Lieut. Samuel M. Marcus Chicago
Capt. Richard E. Heller Chicago	Lieut. Manuel L. Stillerman Chicago
Capt. Harold Laufman Chicago	Lieut. Leonard A. Stine Chicago
	Lieut. Leonard Weinstein Chicago

DR MEYER AWARDED SILVER STAR

Capt. Alired C. Meyer Chicago of the Army Medical Corps has been awarded the Silver Star for heroism and outstanding achievement in operating on wounded soldiers while under Japanese gunfire in New Guinea. He is said to be serving with the first portable hospital to be established by the Army. A portable hospital is understood to be one in which the medical equipment and supplies are so packed and arranged that in jungle warfare they may be carried forward near the front lines, if necessary by hand.

PRISONER OF THE JAPANESE

The first direct word from Capt. Gerald M. Greenspahn formerly of Chicago since Nov. 27, 1941 was recently received by his family indicating that he is being held as a prisoner of the Japanese in the Philippines in prison No. 1. Captain Greenspahn graduated from Northwestern University Medical School Chicago in 1935 and was staff physician of the American Hospital before entering the service.

FLIGHT SURGEONS ASSISTANTS

A class of ninety-nine flight surgeons assistants completed the six weeks course in aviation medicine at the School of Aviation Medicine Randolph Field Texas Aug. 21. Brig Gen Eugen G. Rumartz U. S. Army is commander of the school.

NAVY

COMMISSIONING OF APPRENTICE SEAMEN
IN MEDICAL SCHOOLS ON COMPLETION OF MEDICAL EDUCATION

The Bureau of Naval Personnel of the Navy Department, Washington, D. C., has announced that apprentice seamen, Class V-12(S), who are medical students will, on satisfactory completion of their medical education, be appointed to the rank of Lieutenant (jg), (MC) U. S. Navy, or Lieutenant (jg), MC-V(G), U. S. Naval Reserve, in accordance with the following procedures:

(a) For appointment in the grade of Acting Assistant Surgeon rank of Lieutenant (junior grade), (MC), U. S. Navy:

1 Students, within three months of completion of their junior year and at any time thereafter may submit application to the Bureau of Medicine and Surgery via the commanding officer for examination for appointment as Acting Assistant Surgeon for intern training in the U. S. Navy. Commanding officers of Navy V-12 units at medical schools have been provided with a supply of the appropriate application forms.

2 The Bureau of Naval Personnel, on the recommendation of the Bureau of Medicine and Surgery, will authorize qualified applicants to participate in examinations which will be conducted at all continental U. S. naval hospitals during January, May and September of each year.

3 Candidates will receive official notification via their commanding officer of the results of their examination approximately two months following the date thereof.

(b) For appointment as Lieutenant (junior grade), MC-V(G), U. S. Naval Reserve:

1 Students who did not apply or failed to qualify on examination for a naval internship and have contracted for a civilian internship in lieu thereof will be eligible for this appointment on satisfactory completion of their medical education.

(c) Commanding officers of Navy V-12 units at medical schools are requested to submit to the Bureau of Naval Personnel via the Bureau of Medicine and Surgery sixty days prior to established graduation dates two lists in triplicate of senior class V-12(S) medical students under their command who have been reported by medical school deans as scheduled to graduate. One list should include only the names of those students who have qualified for appointment as Acting Assistant Surgeon for intern training in the U. S. Navy and the second list the names of those students committed to a civilian internship and thus qualified for appointment as Lieutenant (jg), MC-V(G), U. S. Naval Reserve. It is desired that there be incorporated in these reports data constituting the commanding officer's recommendation as to the possession of requisite officer-like qualities in each case together with remarks on the following points:

1 Whether any student who participated in an examination for appointment as Acting Assistant Surgeon has failed to receive official notification as to the results of his examination.

2 Whether each student who has qualified for appointment as Acting Assistant Surgeon intends to accept the appointment on graduation or to decline for the purpose of attending a civilian internship. In the latter case, graduates will be appointed Lieutenant (jg), MC-V(G), U. S. Naval Reserve, and released to an inactive duty status.

3 The names and locations of the hospitals in which Naval Reserve appointees will serve civilian internships indicating the type and duration (dates of commencement and completion) of the internship contracted for in each case.

4 The necessary delay, not to exceed thirty days, in reporting at the initial permanent duty station required by each individual for the purpose of taking state board medical examinations. (In cases in which state board medical examinations will not be completed during the thirty day period following graduation, newly appointed officers will report to assigned stations of duty and, at the appropriate time after reporting, submit a request to the commanding officer of the station to which assigned for such leave as may be necessary to participate.)

Commanding officers of V-12 units at medical schools where graduation dates have been established for October 1943 will forward the lists requested as soon as possible.

(d) The commanding officers are directed to forward a completed report of physical examination, form Y, in duplicate for each student named in the foregoing lists who is recommended for appointment.

(e) On receipt of this report from commanding officers, the Bureau of Medicine and Surgery will make appropriate recommendation by endorsement to the Bureau of Naval Personnel. Appointments will be issued for fully qualified applicants and will be forwarded to commanding officers for delivery on graduation.

(f) Appointments in the grade of Acting Assistant Surgeon for internship with the rank of Lieutenant (junior grade), (MC), U. S. Navy, will be accompanied in each case by active duty orders to the naval hospital to which such appointees have been assigned for intern training.

(g) Appointments as Lieutenant (junior grade), (MC-V(G)), U. S. Naval Reserve, will be written with date of rank approximately ten days after graduation. If appropriate, commanding officers will furnish a transportation request and meal tickets covering return of these men as Apprentice Seamen, class V-12(S) or SV-12(S) to the place to which initial orders to active duty were addressed or they will be granted a travel allowance of 5 cents a mile in lieu thereof in accordance with the provisions of reference (a). These men will be instructed by the commanding officer to appear before a naval officer qualified to administer oaths or before a notary public on the date specified as "date of rank" in order to execute the acceptance and oath of office. The commanding officer shall explain clearly that a man cannot execute an acceptance and oath of office as a naval officer and subsequently use transportation forwarded to him as an enlisted man.

(h) The appointment for any man who fails to graduate will be returned by the commanding officer to the Bureau of Naval Personnel for cancellation and appropriate disposition of the man.

(i) Additional information relative to this subject will be found in references (b) and (c).

FOREIGN LANGUAGE REQUIREMENTS FOR
PREMEDICAL STUDENTS

The Bureau of Naval Personnel of the Navy Department, Washington, D. C., announced on September 9 the interpretation of the foreign language requirements for premedical students as referred to in References (a) V-12 Bulletin No. 1, (b) V-12 Bulletin No. 22, and (c) V-12 Bulletin No. 2.

1 Reference (b), page 12c, language requirement for subject students shall be interpreted as follows:

V-1 and V-7 transfers to V-12, who are pursuing a premedical program shall complete the equivalent of twelve college semester hours of a single foreign language. French, German or Spanish is preferred, but other languages may be substituted at the discretion of the college authorities. A high school unit (one year) is to be considered equivalent to six semester hours.

2 In accordance with reference (c), page 3, paragraph 8 other premedical students entering the V-12 program with advanced standing must meet minimal requirements prescribed for V-1 and V-7 transfers to V-12.

3 Only premedical students entering the V-12 program as freshmen will be required to take the fully prescribed course outlined in reference (a). Attention is invited to the fact that French, German or Spanish is preferred, but other languages may be substituted under exceptional circumstances. Interpretation of "exceptional circumstances" shall be the responsibility of the college authorities.

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

INTERN-RESIDENT PROGRAM FOR HOSPITALS

Considerable confusion seems to have arisen regarding the number of internships and residencies which may be maintained by hospitals under the new intern resident program which has been made possible by the deferment of certain numbers of interns and residents holding reserve commissions in the Army and Navy.

To meet the minimum needs of hospitals nationally twice as many residents as will be deferred by the Army and Navy will be required. The remaining half (those not deferred by the Army and Navy) must be made up of physically disqualified men and women in order to give the hospitals minimum adequate house staff coverage.

This program definitely does not state that a hospital may only or will necessarily retain one third of its interns to serve as junior residents nor does it mean that a hospital may only or will necessarily retain one half of its junior residents as senior residents. These fractions were published to show the overall proportion of commissioned officers now under the jurisdiction of the Army and Navy who would be deferred by the military services to serve as one source of personnel for civilian hospital appointments.

The program does state that, generally speaking hospitals will be able to return about two thirds of their 1940 house staffs, provided there has been no pronounced decrease or increase in patient load since that time. This two thirds will comprise those ineligible for military service as well as those deferred by the Army and Navy.

The first fraction represents the proportion of deferments by the armed forces of commissioned officers (9-9-9). The second figure concerns the allocation—to the hospitals (approximately 66 2/3 per cent of the 1940 staff). Each hospital should procure as many physically disqualified men as possible, and only the remainder unable to be procured from this source can be obtained from those deferred by the Army and Navy.

The hospital questionnaires, which the Procurement and Assignment Service urgently requests hospitals to return, will give the needed information to determine a general basis for estimating the number of interns and residents which each hospital should have on the basis of the 1940-1942 house staff. There will probably be some necessary changes in individual hospitals which have peculiar or particular problems, but the formula will apply to all general hospitals.

MISCELLANEOUS

NATIONWIDE CAMPAIGN FOR QUININE

In a nationwide campaign which began seven months ago for the conservation of quinine for the armed forces, more than eleven million 5 grain doses of quinine have been collected and are now en route to army and navy fighting fronts. The campaign was supported by thousands of retail pharmacists, wholesale druggists and hospitals and exceeded its goal by nearly 50 per cent. More than sixteen thousand packages have been received at the National Quinine Pool, American Pharmaceutical Association Constitution Avenue and Twenty-Second Street N.W. Washington, D. C. The quinine arrived in the form of powder, plain and sugar coated tablets, crystals and liquid and was of both foreign and domestic manufacture. The medical departments of the Army and Navy have assigned pharmacists to assort and classify the contributions which will be accepted until October 15.

NEW FEE SCHEDULE FOR THE EMERGENCY MATERNITY AND INFANT CARE PROGRAM

Under a new fee schedule effective August 18, medical care was authorized for 974 wives and children of enlisted men of West Virginia for the first fifteen weeks operation of the plan proposed by the state health department for the emergency Maternity and Infant Care Program. This plan was approved by the Children's Bureau of the Labor Department in Washington. As of August 19, a total of 361 West Virginia doctors had qualified for participation in this program, which is under the direct supervision of Dr. Lenore Patrick, director of the Division of Maternal and Child Hygiene. Fifty-five approved hospitals were taking part.

SCHOOLS DETERMINE POLICY IN REGARD TO MARRIAGE OF MEMBERS OF THE U S CADET NURSE CORPS

According to the Division of Nurse Education of the U. S. Public Health Service in many schools marriage does not prevent the admission and retention of students. In some schools maternity leave is granted in a few schools married applicants are not admitted and married students are not retained. The fact that a school is receiving federal funds under the Bolton act does not alter a school's policy in regard to marriage. An applicant before enrolling in any school of nursing as a U. S. cadet nurse should understand the school's policy on marriage.

If a school admits and retains married students, the "health permitting" clause in the application signed by the cadet nurse allows the school to provide maternity leave. This clause applies in the same fashion to the graduate nurse who has pledged herself to render essential nursing service throughout the war. Students who are enrolled in schools in which marriage of students is prohibited if they wish to marry before completion of the program, might consider the possibility of transfer to another school although the preferable course to follow would be that of waiting to marry until after graduation.

PUBLIC HEALTH UNDER HITLER

The Greek government has decided to supply all consumptives insured at social insurances with better food consisting of meat, eggs, sugar and butter, *Donauzeitung* Belgrade, July 16, reports. Previously this allowance was granted in grave cases only. In Athens consumptives are estimated to number 20,000.

According to DNB of July 24 a commission sent by the Spanish minister of labor to study the German health insurance system is at present staying in Berlin. The members of the commission have the task of acquainting themselves with the statutory regulations and the organization of German health insurance. The Spanish government intends to introduce a health insurance system in Spain. The Spanish visitors will have the opportunity to study all institutions concerned in the great German reich and in the protectorate and to acquaint themselves with the working of the German health insurance system. The reich minister of labor, Franz Seldte received the members of the commission. In his address he spoke of his pleasure at Spain's intentions to organize a health service for the Spanish workers. The reich ministry of labor would gladly cooperate to help Spain to realize these aims.

12-Uhr Blatt of July 10 prints a description of the largest underground hospital in Berlin. Operations are carried out in this hospital every night in order to be prepared in case of an emergency. Expectant mothers are accommodated here every night and many babies have already been born in this hospital.

Rumania *Curentul* of July 22 states that medical students must do one month's military service plus one month's medical practice during the summer vacation.

ORGANIZATION SECTION

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Change in Status—H J Res 159 has passed the House and has been favorably reported without amendment by the Senate Committee on Appropriations, making available an additional sum of \$18,020,000 to provide obstetric and pediatric care to the wives and infants of enlisted men of the fourth, fifth sixth and seventh grades in the armed forces of the United States. An effort was made on the floor of the House to amend the joint resolution so that the federal money could be made available in the form of allotments to the wives of servicemen, but the amendment was defeated by a vote of 115 to 8.

Bills Introduced—The President has submitted to Congress a supplemental estimate of appropriation for the Veterans' Administration, for the fiscal year 1944, in the amount of \$10,350,000, to provide 3,950 additional beds for neuropsychiatric patients at thirteen existing facilities of the Veterans' Administration (H Doc 280). H R 3204, introduced by Representative Lynch, New York, undertakes to provide a system of old age and survivors' insurance for employees of certain organizations not at present within the coverage of the Social Security Act, such as religious, charitable, educational and scientific organizations. H R 3293, introduced by Representative Peterson, Florida, provides that, notwithstanding any provision of law or veterans' regulation, the pension, compensation or retirement pay of a veteran of the war with Spain, including the Philippine Insurrection and the Boxer Rebellion, shall not be reduced while such veteran is being furnished hospital treatment or institutional or domiciliary care by the United States or any political subdivision. H R 3294, introduced by Representative

Talbot, Connecticut, provides that any blind person who is traveling on a train being operated by any common carrier by railroad subject to the Interstate Commerce Act may keep his seeing eye dog with him in any coach or Pullman car of such train.

DISTRICT OF COLUMBIA

Change in Status—S Res 178 has been agreed to, authorizing the Senate Committee on the District of Columbia to investigate conditions at Gallinger Municipal Hospital, with particular reference to sanitation, food, diet and the treatment and care of tuberculous patients. The committee will be authorized to call on the United States Public Health Service for such professional, technical or other assistance as it may deem necessary for the purposes of the investigation.

Bills Introduced—S 1340, introduced by Senator McCarran, Nevada, proposes to establish a sanitary code governing the operation of restaurants in the District of Columbia. Among other things the bill provides that, when suspicion arises as to the possibility of transmission of infection from any restaurant employee, the health officer will be authorized to require (1) the immediate exclusion of the employee from all restaurants and (2) the immediate closing of the restaurant concerned until no further danger of disease outbreak exists. H R 3314, introduced by Representative Randolph, West Virginia, provides for the disposition of funds collected by District of Columbia examining, licensing and other boards and commissions, including the Commission on Licensure to Practice the Healing Art.

MEDICAL ECONOMIC ABSTRACTS

OHIO RURAL MEDICAL SERVICE PLAN

Several governmental and private organizations asked the Ohio State Medical Society to join in setting up a prepayment medical service plan for farmers in Logan County. The council of the Ohio State Medical Society asked the Public Relations Committee to investigate the situation. The chairman of that committee submitted the following recommendation, which was adopted by the council.¹

"That the council authorize the use of an amount, not to exceed \$15,000, from the reserve fund of the association for the organization and establishment of a medical service plan in

Logan County under the terms of the Ohio Enabling Act, provided the establishment of a plan in that county has the approval and active support of the Logan County Medical Society, that \$10,000 of this amount would be advanced for the purpose of meeting the financial provisions of the Enabling Act and that the balance would be used under the direction of the Committee on Public Relations and Economics for preliminary organizational work and activities."

In submitting the foregoing recommendation, Dr Hen pointed out that the question will be discussed by the Logan County Medical Society as soon as that society is informed as to what assistance, financial and otherwise, the Ohio State Medical Association will contribute.

¹ Proceedings of the Council, Ohio State M J 39 756 (Aug.) 1943

WOMAN'S AUXILIARY

Louisiana

The annual meeting of the Woman's Auxiliary to the Louisiana State Medical Society was held in Baton Rouge recently with the president, Mrs Clarence B Erickson, presiding. Mrs Richard H Clark, president of the Southern Medical Association auxiliary, and Mrs Sam Houston, wife of the governor of Louisiana, were guests of honor. Mrs Houston extended an invitation to all those present to attend a reception at the executive mansion that evening.

Dr Emmet Irwin, president of the Louisiana State Medical Society, visited the auxiliary meeting and outlined plans for

the coming year. Mrs George Taquino is the incoming president and Mrs Rhodes Spedale is the president-elect.

Colorado

The board of the Woman's Auxiliary to the Denver County Medical Society has asked each member to contribute \$2.00 in excess of dues to the student loan and emergency funds this year. The fund will be used to assist medical students who are unable to pass the Army or Navy physical requirements and who are on their own resources to complete a medical education. The emergency fund is to be available for aiding the families of young doctors in service.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Gift for Library—Dr Theodore S Kimball pathologist of the 47th General Hospital group Modesto, recently presented the White Memorial Medical Library of the College of Medical Evangelists, Los Angeles with \$500 to buy books for the hematology section of the library. Dr Kimball was associate professor of pathology at the College of Medical Evangelists.

Universities and the Medical Profession—The San Francisco County Medical Society devoted its September 14 meeting to a discussion of 'The Universities and the Medical Profession'. The speakers were Drs Loren R Chandler, dean, Stanford University School of Medicine, on 'The Place of the Practicing Physician in Medical Schools', Francis Scott Smith, dean, University of California Medical School 'Some Features of Medical Education Under the Present Circumstances' and Donald B Tresidder, president, Stanford University 'Some Major Problems of Education Confronting a Private University Now and in the Postwar Period'.

Public Health Officials and Industrialists Cooperate—A committee called the Industrial Division of the City of Los Angeles and County Defense Council has been formed to bring about a closer understanding by public health officials in the area and the industrialists. The tentative program of the committee aims (1) to establish and maintain an advisory council of public health officers and representatives of the private medical profession (2) to provide a common point of initial contact for industrial management on all problems of industrial health (3) to effect practical procedures for prompt reference of these problems to the proper medical authorities, and (4) to undertake an educational campaign using the press and direct mail to convince industrial management and employees (a) of the importance of preventing interference with the war production program by preventable employee illnesses (b) of the possibility of serious epidemics under present and anticipated conditions of housing and inadequate nourishment and resulting from the migration of workers from other sections of the country where health supervision has not been provided, (c) of the necessity for preemployment medical examination not as a basis of applicant exclusion but first, to aid persons with communicable diseases to contact corrective medical procedures and, second to assure the placement of new employees in occupations suitable to their health status, and (d) of the advisability of providing continuing medical inspections to discount the possibility of the spreading of diseases into industry from outside sources.

DISTRICT OF COLUMBIA

Personal—Mr Edward K Funkhouser has been appointed executive secretary of the District Tuberculosis Association. According to *Medical Annals* Mr Funkhouser has served for the past eighteen years as executive secretary of the Passaic County, N. J., Tuberculosis and Health Association. Dr Charles C Chapple has been appointed chief medical gas officer in the Office of Civilian Defense and Abraham N Franzblau, P. A. Surgeon, U. S. Public Health Service has been relieved as acting medical gas officer to be assigned as assistant to the chief medical officer.

New Blood Donor Center—The dedication of the new District Red Cross blood donor center at the Acacia Building Washington took place on July 31. The center is operated under the direction of the District Red Cross and is staffed by Army and Navy medical officers and Red Cross personnel both paid and volunteer. Lieut Eugene W Higgins (MC), U. S. Naval Reserve is physician in charge. The invocation was delivered by Capt Robert D Workman chief of the navy chaplains and the speakers included Major Gen Norman T Kirk, surgeon general of the U. S. Army, Rear Admiral Harold W Smith (MC) U. S. Navy, and Fred M Vinson director of economic stabilization who read an address by James F Byrnes director of war mobilization. The center is housed in the building of the Acacia Mutual Life Insurance Company which presented space for the center to the Red Cross.

FLORIDA

Time Limit Set to Register Medical Licenses—Licenses to practice medicine in Florida must henceforth be registered within sixty days of the date shown on the license, in accordance with an amendment to the Florida statutes which became effective June 11. The original law required that every license to practice medicine be registered in the office of the clerk of the circuit court of the county in which the licensee resides or in which his practice is intended to be carried on but no time limit was specified. Licenses have been recorded as late as twenty years after the date of issuance. All unregistered licenses which were in effect on June 11 of this year when the new law became effective, must be recorded within six months of that date. It is expected that the new law will help prevent the recording of fraudulent licenses.

ILLINOIS

Occupational Therapy—A new curriculum on occupational therapy has been set up by the University of Illinois. Students will spend their first five semesters of study on the Urbana-Champaign campus and four semesters in the college of medicine, Chicago.

Botulism Antitoxin Now Available—The state department of public health is now making available to Illinois physicians, without charge botulism antitoxin combined types A and B, for emergency use in the care of persons who have eaten food that is so poisoned. The antitoxin may be obtained from the department's offices at Springfield and from the department's laboratories at Carbondale, Champaign and Chicago.

Dr Fitzgerald Named Supervising Ophthalmologist for Public Aid Commission—Dr James Robert Fitzgerald, clinical associate in ophthalmology, Loyola University School of Medicine, Chicago has been appointed supervising ophthalmologist of the Illinois Public Aid Commission. In this capacity he will review the reports made of examining ophthalmologists on applicants for aid under the blind assistance program and will determine the eligibility of these applicants on the basis of loss of sight. He will also provide the commission's staff with technical advice on general policy and on individual problems in the administration of the program. Initial grants under the program, which is being financed jointly by the state and federal governments, were to be started on October 1. Under the program aid will be furnished on the basis of need to blind residents of Illinois who are 18 years of age and over. Where possible treatment will be given to restore the sight of recipients of this aid. Special efforts will be made to assist recipients to become self supporting.

Chicago

Dr William Hibbs Made Medical Director at Presbyterian—Dr William G Hibbs, associate clinical (Rush) professor of medicine, University of Illinois College of Medicine has been appointed medical director of Presbyterian Hospital. He began his work on August 1. Dr Hibbs graduated at Rush Medical College in 1920 and served his internship at Presbyterian where he has been a member of the regular staff since 1925. He represents the American Medical Association on the joint committee on hospital library service.

Nutrition in Wartime—The Institute of Medicine of Chicago will conduct a postgraduate assembly on 'Nutrition in Wartime' November 17-18. The program will be devoted to phases of nutrition that are of particular interest to practicing physicians, dentists, nutritionists and dietitians. Among the speakers will be:

- Frank L Gunderson, Ph.D., Washington, D. C., 'The Impact of the War on the Diet of the City and Rural Dweller.'
- Dr Leonard G Rowntree, Washington, D. C., 'The State of Nutrition in Urban and Rural Populations as Reflected by Selective Serum Rejection.'
- Dr John B Youmans, Nashville, Tenn., 'Early Clinical Recognition of Nutritional Deficiencies.'
- Dr Paul R Cannon, Chicago, 'Some Pathologic Aspects of Under-nutrition.'
- William A Perlzweig, Ph.D., Durham, N. C., 'Laboratory Aids in the Evaluation of Nutritional Deficiency.'
- Ledia J Roberts, Ph.D., Chicago, 'Present Day Concepts of Nutritional Requirement.'
- William C Roe, Ph.D., Urbana, Ill., 'The Role of Protein in the Diet.'
- Dr George H Whipple, Rochester, N. Y., 'Food Protein: Biological Tests and Dietetic Therapy.'
- Dr Samuel Sokol, Chicago, 'The Role of Calcium in the Diet.'
- Dr Anton J Carlson, Chicago, 'Some Obstacles in the Path to a Daily Optimum Diet.'
- Dr Julian D Boyd, Iowa City, 'Teeth as an Index of Nutritional Deficiency.'
- Maya Hoobler, Ph.D., Detroit, 'Nutritional Requirements in Pregnancy and Lactation.'
- Dr Edward H Kneass, Rochester, Minn., 'Overweight and Underweight.'
- Dr Henry T Rickett, Chicago, 'The Use of Calorimetry in the Treatment of Disease.'
- Dr Morris Fishbein, Editor of THE JOURNAL, 'Uses and Abuses of Vitamins.'

There will be six panel discussions on therapeutic diets and rationing, current practices in infant feeding, parenteral nutrition, methods and indications, the proper place of accessory vitamins in the diet, dental caries in the young and in pregnant women, be controlled by diet? and controversial aspects of diet in diabetes. Another feature will be a "Nutrition Information Please" with Dr. Fishbein acting as moderator and Drs. Gunderson, Perlzweig, Rose, Rowntree, Whipple and Youmans comprising the board of experts.

INDIANA

Dr. Lawson Observes Ninety-Fourth Birthday—Dr. Wilson L. Lawson, Danville, said to be the oldest practicing physician in Indiana and the oldest living graduate of Wabash College, Crawfordsville, observed his ninety-fourth birthday on September 3. Dr. Lawson is health officer of Hendricks County and still takes care of his own office work, making some calls, newspapers report.

Personal—Frank G. Laird, who has been acting as president of the Indianapolis Board of Health since the retirement of Dr. Maurice J. Barry, was elected president of the board at the annual business meeting on July 16. Dr. Leonard A. Insinger was elected vice president and Dr. Herman G. Morgan was elected secretary and city health officer for the thirty-second year.—Dr. Charles C. Crampton, Delphi, on June 22 observed his completion of fifty years in the practice of medicine. His associates in the Arnett-Crockett Clinic in Lafayette presented him with a diamond pin denoting that he had served as commander of the American Legion. He has been a past president of both the Monon and Wabash railroads associations, of the county medical society and of the eleventh councilor district of the state medical society.—Dr. Stanley A. Dowiat, Cicero, Ill., has been appointed superintendent of the Smith-Esteb Memorial Hospital, Richmond, to succeed Dr. Henry Vernon Madsen, resigned.—Philip S. Wunick, formerly of Stamford, Conn., has become director of research of Pitman-Moore Company, Indianapolis, pharmaceutical and biologic manufacturers.

MASSACHUSETTS

Dr. Harry Solomon Named Professor of Psychiatry at Harvard—Dr. Harry C. Solomon, clinical professor of psychiatry, has been appointed professor of psychiatry at Harvard Medical School and medical director of the Boston Psychopathic Hospital, succeeding the late Dr. C. Macfie Campbell. Dr. Solomon graduated at Harvard in 1914 and has been on the faculty there since 1915.

Grant for Work in Immunochemistry—The Rockefeller Foundation has awarded a grant to William C. Boyd, Ph.D., associate professor in biochemistry, Boston University School of Medicine, to enable him to continue his research work in immunochemistry for a two year period. A former grant received from the Guggenheim Foundation enabled Dr. Boyd to do original research in Egypt. He graduated at Harvard University, Boston, in 1925. He has been a teaching fellow in the Boston University School of Medicine since 1926 and received his Ph.D. there in 1930.

MICHIGAN

Personal—Dr. Edward L. Collins, Grand Rapids, has been appointed superintendent for the Michigan Institute for the Blind at Saginaw. Dr. Collins has been blind since a child.—Dr. Albert A. Hughes, Detroit, has been elected Most Worshipful Grand Master of Michigan Masonry.—Dr. David H. Burley recently completed fifty years of practice in Almont, he is also a registered pharmacist.—Dr. Wesley H. Mast, Petoskey, has been appointed a member of the state advisory council of health for a six year term ending June 30, 1949.—Dr. Leslie E. Coffin, Painesdale, was installed as president of the Upper Peninsula Medical Society at its recent meeting in Iron Mountain and Dr. Nathan J. Frenn, Bark River, was chosen president-elect. Dr. Robert J. McClure, Calumet, secretary of the Houghton-Baraga-Keweenaw County Medical Society, will be the secretary of the Upper Peninsula Medical Society during the ensuing year.

Committees on Workers' Health—The Michigan State Medical Society and the United Auto Workers have agreed to set up committees to confer on medical and health problems of Michigan's industrial workers, newspapers report. Members of the committee appointed by the state medical society include Drs. Robert L. Novy, Detroit, chairman, Gustave L. McClellan, Detroit, Patrick L. Ledwidge, Detroit, Earl F.

Carr, Lansing. Samuel W. Donaldson, Ann Arbor, and Otto K. Engelke, Ann Arbor. The formation of the United Auto Workers C. I. O. committee had not been completed at the time of this report, but tentative plans indicated that George J. Addes, secretary-treasurer of the U. A. W.-C. I. O., will be ex officio chairman. The arrangement was worked out after an appeal had been submitted to the medical society by the union for a list of medical and surgical specialists who would accept patients referred by the union's own medical department.

MISSOURI

Personal—Robert Bruce Moffett, Ph.D., since 1941 post doctorate research associate at Northwestern University, has been appointed senior research chemist in the laboratories of George A. Breon & Company, Kansas City.—Dr. Richard E. Banner, Kansas City, has been named head of the health unit in Johnson County with headquarters at Warrensburg.

Grant to Finance Research in Caudal Anesthesia—The U. S. Public Health Service has made a grant to Washington University School of Medicine, St. Louis, to help finance a cooperative study of the gross anatomy of the spinal dura mater and the conformation of the posterior surface of the sacrum. The project is under the supervision of Mildred Trotter, Ph.D., and Dr. Virginia S. Lamer of the department of anatomy and Dr. Howard E. McKnight of the department of obstetrics and gynecology. It is anticipated that the results will be a contribution to the procedure of the administration of continuous caudal anesthesia in childbirth.

NEW JERSEY

State Department Creates Tuberculosis Division—The New Jersey State Department of Health has organized a division of tuberculosis to combat a sharp increase in the disease in the industrial areas. According to the Bulletin of the National Tuberculosis Association, 507 cases of tuberculosis have been found in 42,000 chest x-ray films taken in nine industrial areas of the state.

Industrial Physicians Wanted—The Department of Health of the State of New Jersey, Trenton, whose industrial health activities have expanded rapidly during the present war, has announced its need for two full time industrial hygiene physicians for its industrial hygiene service. The principal duties of the selected physicians will be consultations in regard to the control of occupational diseases, industrial toxicologic problems, evaluation of adequacy of plant medical services, promotion of measures which will reduce absenteeism from non occupational causes, and conduct of industrial health education activities.

NEW YORK

Fifty Years of Practice—The *News Letter* of the Suffolk County Medical Society for September was dedicated to members who had completed a half century in the practice of medicine and who participated in a celebration in July. The members who were honored include Drs. William Newton Barnhardt, Toronto, Ont., George Herbert Carter, Huntington, William Elliott Foster, Babylon, Frank Diah Peterson, Cutchogue, and Frank Overton, Patchogue.

Personal—Dr. Theodore G. Klumpp, president of the Winthrop Chemical Company, has been elected a member of the Academia de Ciencias Medicas, Fisicas y Naturales de la Habana, Cuba. Presentation of the academy's medal will take place at a future date in Havana, where Dr. Klumpp will go to deliver a scientific paper.—Dr. Thomas M. Holmes, Delmar, has been appointed a member of the medical board of the State Employees Retirement System, succeeding Dr. Clarence E. Mullens, Albany.

Dr. Burton Simpson Retires from State Institute—Dr. Burton T. Simpson, director of the State Institute for the Study of Malignant Diseases, Buffalo, retired on August 1 after having reached the compulsory retirement age. He had been in the service of the state since 1910, first as resident pathologist of the institute and since 1924 as its director. In 1931 he was appointed director of the newly created division of cancer control, combining the duties of that position with those of the administration of the institute. He continued until 1939, when the division was reorganized and its headquarters transferred to Albany, primarily to amplify the resources available to practicing physicians throughout the state for the diagnosis and care of cancer. Since then Dr. Simpson has devoted full time to administering the institute. He was president of the American Society for the Control of Cancer, 1935.

PENNSYLVANIA

University Bulletin Honors Oldest Graduate—The *Pennsylvania Gazette*, official journal of the University of Pennsylvania, Philadelphia, paid special tribute in its September issue to Dr John A. Iell, Doylestown, who is 93 years of age and the oldest living graduate of the university's medical school. Dr Iell graduated at the medical school in 1874. He is also the oldest living graduate of Lafayette College, which he attended two years before entering Pennsylvania. After graduating from the Doylestown English and Classical Seminary Dr Iell taught school for two years and was principal of the Hugheston Free School, Buckingham. He not only has served his community for many years as a practicing physician but also has been a member of the Doylestown School Board, the Doylestown Board of Health and at one time served as assistant surgeon of the Sixth Regiment of the Pennsylvania National Guard. In 1933 the state medical society paid tribute to him in recognition of his fifty-nine years of medical service faithfully performed to his community in the traditional ideals of the medical profession.

Pittsburgh

Colonel Dabney Named Assistant Dean—Col Albert S. Dabney, M. C., U. S. Army, assistant commandant of the Medical Field Service School at Carlisle Barracks, Pennsylvania, has been appointed assistant dean at the University of Pittsburgh School of Medicine, effective October 1. Colonel Dabney was relieved from his duties at Carlisle Barracks on August 31 in order to take advantage of accrued leave before being placed on the compulsory retirement list, November 30 at the age of 64. Col Guy B. Dent, M. C., U. S. Army, who recently returned from a six months tour of duty as chief surgeon of a base section in the African theater of operation, will temporarily replace Colonel Dabney as assistant commandant at the field service school. A ceremonial retreat parade was held on August 31 in honor of Colonel Dabney, and Brig Gen. Addison D. Davis, commanding general of Carlisle Barracks, commended Colonel Dabney for his loyal and efficient services. A veteran of two world wars and a medical officer for twenty-seven years, Colonel Dabney had been at Carlisle Barracks since June 27, 1939, first as director of the medical department equipment laboratory and on Jan. 10, 1942 as assistant commandant. Previous to his service at Carlisle Barracks he had been executive officer in the Surgeon General's Office at Washington D. C.

SOUTH CAROLINA

Personal—Dr Luther A. Riser, Sedgefield, N. C., has been named director of the bureau of vital statistics of the state board of health to succeed Dr Martin B. Woodward, Aiken, who resigned to accept a similar position in West Virginia.—A bronze bust of Dr Frank H. McLeod, founder of the McLeod Infirmary at Florence, was recently presented to the infirmary to mark his many years' service to the community. Although not in practice, Dr McLeod still serves as medical superintendent of the infirmary.

Refresher Course—The Alumni Association refresher course of the Medical College of the State of South Carolina, Charleston, inaugurated last year, will be held November 3-4 at the Baruch Memorial Auditorium, Charleston. Speakers will be:

Dr Harrison F. Flippin, Philadelphia. The Uses and Abuses of the Sulfonamides.
Dr Charles C. Wolferth, Philadelphia. Differential Diagnosis of the Anginal Syndrome.
Dr Leroy U. Gardner, Saranac Lake, N. Y. The Essentials of Pneumoconiosis.
Dr Alfred Blalock, Baltimore. Traumatic Shock.
Dr Virgil P. W. Sydenstricker, Augusta, Ga. Deficiency Diseases.
Dr George W. Thorn, Boston. Physiologic Considerations in the Treatment of Nephritis.
Dr J. T. King, Washington, D. C. Calcific Aortic Stenosis.
Dr Roy R. Kracke, Emory University, Ga. Diagnosis and Treatment of the Hemorrhagic Diases.

There will be round table discussions on 'The Sulfonamides', 'Treatment of Heart Disease', 'Pulmonary Diseases' and one on 'Thyroid Disturbances'. Surgical round table discussions will be held as will pathologic conferences. At the founder's day banquet, Thursday evening, Dr Henry E. Melenev, New York, will discuss Tropical Medicine Present and Future.

Investigation of Medical Education and Medical Service Launched—The investigation of medical education and medical service in South Carolina started on August 25 in the senate chamber when a specially selected joint committee met to begin the taking of testimony. The committee is composed of Senators James E. Leppard, Chesterfield, chairman; O. T. Wallace, Charleston; and C. S. McCall, Marlboro. Representatives J. Claude Fort, Cherokee, and James B. Mor-

rison, Georgetown, and from the medical association Dr Walter R. Mead, Florence, and Dr William R. Wallace, Chester. Morning and afternoon sessions were held. It is expected that another meeting will be held in Charleston and probably a third in Columbia, after which a report will be made to the general assembly in January. The committee, under a resolution creating it, is to ascertain the cause of 'present acute shortage of medical doctors and medical services in this state' and recommend 'such measures as shall be necessary to procure and maintain an adequate supply and proper distribution of physicians and surgeons' and also to determine whether the state medical college in Charleston 'should be enlarged so as to provide a sufficient supply of medical doctors to serve the needs of the state' and also whether a medical college should be established at the University of South Carolina. The committee is also to determine 'whether it is necessary or desirable that the state should subsidize the cost' of educating medical students and whether it is necessary 'for the state to provide in whole or in part public medical services'. Among those appearing before the committee at this first meeting were Dr Robert Wilson, dean of the medical college of the state; Dr Kenneth M. Lynch, chairman of the state board of health; and Dr Carl B. Epps of Sumter (THE JOURNAL, July 10, p. 757).

TENNESSEE

New Health Set Up in Nashville—Dr Thomas V. Woodring, assistant health officer of Nashville for more than fifteen years, has been appointed director of health of Nashville, a position recently created under a revision of the charter for the city. Dr John Overton will continue as city health officer. The creation of the position of director of health was a recommendation of the public administration service to obtain a better and more efficient government.

Personal—Mrs Dorothy Davis Bryan, Nashville, has been appointed to succeed the late Dr Hale E. Cullom as director of sight conservation and prevention of blindness for the state of Tennessee.—New appointments to the Public Health Council include those of Dr Walker L. Rucks, Memphis and Dr Thomas R. Ray, Shelbyville. Dr Rucks succeeds Dr Webster B. Key, who is now a lieutenant commander in the U. S. Naval Reserve.—Dr David Galloway, Memphis, has been appointed superintendent of the Western State Hospital.

WISCONSIN

Physician Named to New Veteran Recognition Board

—Dr Charles A. Dawson, River Falls, has been appointed by Acting Governor Goodland as a member of the newly created Veteran Recognition Board. The state medical journal reports that the board will have charge of handling the \$6,300,000 earmarked by the legislature for the educational, medical and economic rehabilitation of World War II veterans of Wisconsin and their families, as well as any other state or federal funds set aside for such rehabilitation. Members of the board will receive no salary for their services but will be paid their expenses. A director and staff will be created to administer their funds, the staff to be under civil service.

The Dr. William Beaumont Foundation—At the first meeting of the Dr. William Beaumont Memorial Foundation in Prairie du Chien, September 18, Dr William D. Stovall, Madison, director of the state laboratory of hygiene, was elected chairman of the board of directors and M. J. Dvurd, Prairie du Chien, was chosen president. The foundation was incorporated in May and its purpose is to perpetuate the name and memory of Dr. Beaumont and his memorable experiments in the physiology of digestion and to recognize noteworthy contributions made by other physicians and surgeons of the United States. Organization of the foundation was planned and carried through by the Crawford County Medical Society and the local Kiwanis club. Other officers include Dr. Olaf E. Satter, vice president; Dr. Thomas F. Farrell, treasurer; and J. Alvin Druvor, secretary, all of Prairie du Chien. Other members of the board of directors are Mayor F. W. Clanton, F. A. Otto and Paul H. Schmidt, all of Prairie du Chien; Walter J. Neek, Ph.D., acting dean of the University of Wisconsin Medical School, Madison; was appointed chairman of the advisory board by the directors at their meeting after the membership meeting. Other appointments made by the board of directors were Cal Peters, curator; Dr. Peter L. Scanlin, Dr. Henry H. Kleinpell, Dr. John I. Kane, Dr. Charles A. Armstrong and Dr. Emil H. Leichtenberg, medical advisers to the curator; and Mr. Dvurd, general manager. The first meeting of the new foundation was held in the hospital section of the second Fort Crawford built in 1829 in which Dr. Beaumont served as post surgeon under Col. Zachary Taylor. He was commandant at the fort. This building which is now used as

the city of Prunus du Chien and leased by the D. A. R., is being considered as the home of the foundation. Tentative plans call for the restoration of the building to its original state as it was when Dr. Beaumont was in charge. Dr. Beaumont performed fifty-six of his noted experiments on Alexis St. Martin in the hospital section of Fort Crawford between 1826 and 1832. A number of important books and papers of Dr. Beaumonts are available in Prunus du Chien and will be turned over to the foundation when it has a suitable home.

GENERAL

Better Parenthood Week—The sixth annual Better Parenthood Week will be observed nationally, October 25-31. Parent-teacher, child care, welfare and various civic organizations and study groups will cooperate through programs dealing with parent and child care problems, especially those which confront the nation during wartime.

International Medical Assembly—The twenty-eighth annual International Medical Assembly of the Inter-State Postgraduate Medical Association of North America will be held at the Palmer House, Chicago, October 26-29, under the presidency of Dr. Frank H. Lahey, Boston. Among the speakers will be

Dr. Edmund B. Spruth, Philadelphia, Removal of Metallic Foreign Bodies from the Eyeball and from the Orbit
Dr. James L. Poppen, Boston, The Management of Ruptured Intervertebral Disks
Dr. George B. Listerman, Rochester, Minn., The Treatment of Gastric and Duodenal Ulcer
Dr. Fraser B. Gurd, Montreal, Canada, Treatment of Burns
William H. Hurdless, Ph.D., Indianapolis, Precautions Against the Introduction of Tropical Diseases into the United States
Dr. Major G. Seely, St. Louis, The Gallium Problem in Surgery and Its Solution

At the assembly dinner Dr. Lahey will discuss "Some of the Problems of the War" and Brig. Gen. Fred W. Rankin, M. R. C., "Current Considerations of Postgraduate Medical Education."

Dearholt Medal Awarded—Will Ross, president of Will Ross, Inc., Milwaukee, was presented on September 8 with the Dearholt Medal awarded annually by the Mississippi Valley Conference on Tuberculosis. The medal is awarded for outstanding work and service in combating tuberculosis. Mr. Ross was a patient in a sanatorium founded by the late Dr. Hoyt E. Dearholt, for whom the medal is named, and in 1911 published a book titled "My Personal Experience with Tuberculosis." New officers of the Mississippi Valley Conference include Mrs. Blanche H. de Koning, executive secretary of the Grand Rapids Anti-Tuberculosis Society, Grand Rapids, Mich., president, Dr. Robert H. Hayes, Chicago, a member of the board of directors of the Tuberculosis Institute of Chicago and Cook County, vice president, and A. W. Jones, executive director of the St. Louis Tuberculosis and Health Society, St. Louis, secretary-treasurer. Officers of the Mississippi Valley Trudeau Society, which met jointly with the conference, are Dr. Loren L. Collins, Ottawa, Ill., president-elect, Dr. Henry S. K. Willis, Northville, Mich., president, Dr. Oscar Lotz, Milwaukee, vice president, and John H. Scavlen, Cincinnati, secretary-treasurer.

American Public Health Association—The seventy-second annual business meeting of the American Public Health Association and its wartime public health conference will be held at the Hotel Pennsylvania, New York, October 11-14. An extensive program has been prepared covering public health and including general sessions and section meetings. A special session will be held Tuesday afternoon on "New Ventures Toward Health Security," at which the speakers will include Nathan Sinai, D.P.H., Ann Arbor, Dr. John J. Heagerty, Ottawa, Ont., and Homer Folks, LL.D., New York. "Latin America Looks Toward the Future" will be discussed by a speaker to be announced later. A second special session will be held Wednesday on "Public Health Implications of Tropical and Imported Diseases" at which the speakers will be Dr. Henry E. Meleney, New York, Dr. Wilbur A. Sawyer, New York, Surg. Gen. Thomas Parran of the U. S. Public Health Service, and one other to be announced later. On Wednesday afternoon a special session will be devoted to "Current Health Department Problems in War," the panel leader to be Dr. Huntington Williams, Baltimore. Thursday a special session will be devoted to "The Evolving Pattern of Tomorrow's Health," the speakers to be Dr. Joseph W. Mountin, Washington, D. C., Dr. William P. Shepard, San Francisco, C. E. A. Winslow, Dr. P. H., New Haven, Conn., Henry F. Vaughan, Dr. P. H., Ann Arbor, and Dr. Felix Hurtado. Other features at the meeting will include symposiums on cancer, on the impact of the war on sanitary engineering, the recent

developments in sanitary engineering, postwar opportunities and responsibilities of the sanitary engineer and on gonorrhea. Other speakers will include

Selmann A. Waksman, Ph.D., New Brunswick, N. J., Antibiotic Substances: Production by Microorganisms, Nature and Mode of Action
Colonel Edgar L. L. Hume, M. C., U. S. Army, The Problem of Rickettsial Diseases Among the Armed Forces
Dr. Felix J. Underwood, Jackson, Miss., Planning Today for Public Health Administration Tomorrow
Dr. Carl A. Wilzbach, Cincinnati, Results of Medical and Dental Examinations of 2,500 Senior High School Students
George R. Cowgill, Ph.D., New Haven, Conn., Nutrition—A Factor Important for Industrial Hygiene
Dr. Frank G. Boudreau, New York, Food and Nutrition Policy Here and Abroad

Other groups meeting at this time will include the American School Health Association, the American Social Hygiene Association and on Monday an inter-American conference on health education.

Academy of Ophthalmology and Otolaryngology—The annual session of the American Academy of Ophthalmology and Otolaryngology will be held at the Palmer House, Chicago, October 10-13, under the presidency of Dr. James A. Babbitt, Philadelphia. Among the speakers will be

Dr. Harry S. Griddle, Chicago, A Program of Ophthalmic Service for Small Plants
Dr. Alton E. Briley, New York, Epidemic Keratoconjunctivitis: Results of Therapy
Dr. Walter B. Lincoaster, Boston, The Present Status of Eye Exercises for Improving Visual Functions
Dr. William F. Hughes Jr., Baltimore, Chemical Burns of the Eyes
Dr. Robert Von Der Heydt, Chicago, A Clear Corneal Implant Acquires Dystrophy from Its Host
Olof Larzell, Sc.D., Portland, Edward McCrady Jr., Ph.D., Sewanee, Tenn., and Dr. John F. Larzell, The Development of the Organ of Corti in Relation to the Inception of Hearing
Dr. Anderson C. Hilding, Duluth, Minn., The Role of Ciliary Action in Production of Pulmonary Atelectasis and Vacuum in Sinuses
Dr. Stuart C. Cullen, Iowa City, Anesthesia in Otolaryngology

On Sunday a feature will be a symposium on "Seeing, Hearing, Thinking and Doing—A Problem of American Youth," presented by Drs. Joseph E. Raycroft, Princeton, N. J., Albert D. Ruedemann, Cleveland, and Albert C. Furstenberg, Ann Arbor, Mich. Sunday evening there will be the fourth annual symposium on orthoptics conducted by the American Association of Orthoptic Technicians. In addition to the scientific papers there will be a series of conference periods for members of the academy, continuance courses and a series of motion picture films.

FOREIGN

Social Security in New Zealand—New Zealand's ambitious social security setup is costing the government only one third the sum expected, Health Minister Arthur H. Nordmeyer, chairman of the House of Representatives committee which first endorsed the plan five years ago, declared in a review of the first four years of its operations. Before the social security plan went into gear New Zealand was paying out around \$23,000,000, at current exchange rates, in yearly pensions. All these except war pensions are now a liability of the social security fund. In addition, that fund now pays out bonuses to industry under employment promotion plans, and benefits to unemployed, according to the *New York Times*. The *Times* stated that the principal field in which social security has exceeded expected costs is that in which the government was warned it would do so—the hospital field. New Zealand has the habit of putting sick soldiers into nonmilitary hospitals, which has added to the strain and helped raise costs at the expense of owners of real estate, on which local government taxes are raised to meet one third of the annual charges. Another third is met by a national government grant from general taxation, and the remaining third, or rather less, from the social security fund, it was stated. The *Times* further reported that this practice might be thought to obscure the results of the social security plan in its public health aspects. According to the report "Dr. John Cairney, medical superintendent of Wellington Hospital, stated eighteen months ago that 'even without military patients all beds and facilities would be taken up by patients on the long waiting list.' The fact is that the health plan has never operated fully since it was started, owing to the shortage of doctors and hospital accommodation, and government spokesmen have admitted that wartime pressure has kept down its cost. Shortage of physicians has also kept family doctors from doing the tremendous business which was expected when medical consultation became free. Shortage of materials and labor has helped keep down hospital costs as high as these are today. Minister Nordmeyer recently told the government newspaper the *Standard* that 'during the depression many hospitals allowed building programs to fall behind and when faced with the need for emergency accommodations for the civilian population they found themselves suddenly committed to quite extensive alterations and additions'."

Foreign Letters

LONDON

(From Our Regular Correspondent)

Aug 13 1943

Functional Diseases of the Colon and Rectum

Opening a discussion on functional diseases of the colon and rectum at the Section of Proctology of the Royal Society of Medicine, Sir Arthur Hurst said that the conditioned reflex which led to regular morning defecation might begin in the education of the infant and develop in such a way that the normal individual as he got older did not think about it at all. The most common cause of constipation, especially in women, was neglect of the normal call to defecate. If not acted on, the muscular wall of the rectum relaxed and the desire disappeared and did not return until the next quantity of feces passed into the rectum. With persistent neglect of the call the rectum became completely relaxed and distended. Well over half the cases of constipation were due not to any deficiency in the activity of the colon but to interference with the reflex. Another large group of people imagined themselves constipated when they were not. Many would report that they had a liquid stool and for years had not passed a solid one. They had been taking the aperients which figured so largely in advertisements. The symptoms of autointoxication were not produced by constipation but by the diarrhea due to the aperients taken. Another cause of upset of normal bowel activity was the procedure common some years ago and now revived—not the old fashioned Plombieres douche but successive washings by one pipe after another, taking perhaps a couple of hours, in the vain expectation that eventually clear water would be returned. The procedure ignored the physiologic fact that feces were constantly coming down and mixing with the water. Mucus could be regarded as significant of a pathologic condition only if present with spontaneous diarrhea. With a loose stool caused by an aperient it was merely a protective secretion and of no importance. Mucous colitis was an imaginary complaint based on a wrong diagnosis, it was due to the idea that the presence of mucus was itself significant of disease.

The taking of aperients was the commonest cause of the low abdominal pain associated with spasm. But when such conditions as real ulcerative colitis and diverticulitis were excluded there remained a small number of cases in which colon spasm was the primary thing—a condition corresponding in some ways to asthma and not easy to diagnose or treat. He warned strongly against X-ray examination as a method of diagnosis.

Hurst finally mentioned paroxysmal proctalgia first described as rectal crises of nontabetic origin. At intervals the patient had severe pain, always perineal, not at the anus but apparently 3 or 4 inches up the rectum. Usually it departed spontaneously after ten to fifteen minutes. It was not associated with any particular condition of the bowel but often with sexual activity. It was almost certainly due to a muscular contraction, probably at the junction of the pelvic colon and rectum. Physicians who were patients had obtained relief by having an enema syringe at their bedsides and blowing air up into the rectum.

Leprosy in the British Empire Today

At the annual meeting of the British Empire Relief Association the incidence of leprosy in Nigeria was reported to be high, the cases being estimated at over 200,000. In northern Rhodesia the work started there by certain missionary societies on lines suggested by Dr Ernest Muir, medical secretary of the association, had been satisfactory. In a medical address Major General Sir Cuthbert Sprawson reviewed the progress made during the nineteen years since the foundation of the association. He contrasted the leprosy asylum in India then

with that of today. The care of patients had greatly improved, the scientific classification of cases, their laboratory investigation and efficient treatment were now matters of routine. Patients were kept usefully employed and the atmosphere was one of hope, stimulated by the sight of many leaving the hospital fit to return to the outside world. The improvements in treatment included Rogers's introduction of active derivatives from the oil of various species of *Hydnocarpus* seeds, better method of educating the native population in the disease and the proper mode of living for those who had contracted the disease, and increased knowledge of nutrition, malnutrition being a predisposing cause. The purely laboratory side of research on the whole yielded disappointing results, but the new leprolin and the iodide test had proved of value. More leprosy settlements and clinics were required, also separate institutions for those who had passed through the contagious stage but were too old and feeble to work. They occupied room in hospitals which was required for cases needing more urgent treatment.

Filling the Gaps in Medical Libraries After the War

In a letter to the *Times* C. C. Barnard, librarian of the London School of Hygiene and Tropical Medicine, describes the position of learned and scientific libraries as faced with the problem of attempting to fill gaps in their sets of periodicals due to the war. As stocks in European countries may also have suffered there may not be sufficient copies to go round. To prevent an unseemly scramble by the libraries for the available copies it is desirable that a representative and impartial body should decide, on a national scale, to which institutions the available copies should be allotted. This allocation should form part of a much larger scheme whereby the present holdings of learned periodicals in all libraries would be surveyed and, where necessary, redistributed in the interest of research. The obvious body to do this is the Library Association though the actual work might be most economically done at the National Central Library. Not until this task is completed will it be possible to compile a satisfactory union catalogue of periodicals in British libraries.

Friendly Societies and the Beveridge Scheme

In previous letters the views of the medical profession have been given regarding the Beveridge scheme. As a result of what is described as a successful and profitable meeting with members of Parliament, the National Council of Friendly Societies announces the fundamentals on which it would be willing to collaborate. The following five essentials have been tabulated and are in the hands of the government ministers concerned. 1 The scheme must be susceptible of responsible administration by friendly societies. 2 It must provide for effective self government by members of the society. 3 The rates of benefits and contributions must be such as to allow a reasonable margin for voluntary insurance. 4 There must be direct contact between societies and the insured population. 5 Medical certificates must be issued free of charge to insured persons.

First Aid for Fractured Spine

Some difference of opinion has been expressed as to whether a person suspected to be suffering from fracture of the spine should be carried in the prone position. The question of first aid in such cases has been submitted to the British Orthopedic Association. After discussion at the last meeting the following opinion was given. The executive committee decided to give authoritative support to the view that patients with suspected spinal fracture should be shifted and moved in such a way as not to be folded either backward or forward. The patient should be disturbed as little as possible being transported as he lies. From the point of view of the spinal injury we are of the opinion that there is no indication for change of position from face to back or vice versa.

Deaths

William Fessenden Wesselhoeft, Jr., M.D., Harvard Medical School, Boston, 1887, formerly professor of clinical surgery at the Boston University School of Medicine, fellow of the American College of Surgeons and a member of the Boston Surgical Society, served in France as a lieutenant colonel and as a commanding officer of Base Hospital number 41 during World War I, introduced a new surgical knot and devised a method of sterilizing catgut that was long in use at the Massachusetts Memorial Hospitals, Boston, consulting surgeon to the Memorial Hospitals, where he at one time worked his way through the grades to the position of surgeon, and where he died, June 27, aged 81, of arteriosclerosis and chronic myocarditis.

Edward William Jones & Mitchell S. D., Northwestern University Medical School, Chicago, 1906, past president of the South Dakota State Medical Association and the Mitchell District Medical Society, served overseas as a captain in the medical corps of the U. S. Army during World War I, coordinator of Civilian Defense and examining physician for the Selective Service Board of Davison County, on the staffs of the Methodist State and St. Joseph hospitals, for many years examining physician for the Milwaukee Railroad, treasurer of the city library board, aged 64, died, July 5, of coronary occlusion.

Harland W. Long, Mattoon, Ill., Missouri Medical College, St. Louis, 1898, University and Bellevue Hospital Medical College, New York, 1904, member of the Illinois State Medical Society and the American Psychiatric Association, veteran of the Spanish-American and World wars, received a medal from the French government for his fight against an epidemic of influenza, formerly associated with the U. S. Veterans Bureau, Pittsburgh, and on the staff of the Veterans Administration Facility in Aspinwall, Pa., aged 73, died, July 18, of myocardosis.

Stoddard Linnaeus Anderson, De Kalb, Ill., Rush Medical College, Chicago, 1896, member of the Illinois State Medical Society, member of the draft board, on the staffs of the De Kalb Public and St. Mary's hospitals, De Kalb, and the Sycamore (Ill.) Municipal Hospital, aged 67, died, July 10, in Chicago of diverticulitis of the sigmoid.
